(54) **Pressure gradient CVI/CVD apparatus, process, and product**

(57) The invention relates to the field of high temperature composites made by the chemical vapor infiltration and deposition of a binding matrix within a porous structure. The invention is particularly suited for the simultaneous CVI/CVD processing of large quantities (hundreds) of aircraft brake disks.

EP 0 832 863 A2

Description

Background of the Invention

5 The invention relates to the field of high temperature composites made by the chemical vapor infiltration and deposition of a binding matrix within a porous structure. More particularly, the invention relates to pressure gradient processes for forcing infiltration of a reactant gas into a porous structure, apparatus for carrying out those processes, and the resulting products.

10 Chemical vapor infiltration and deposition (CVI/CVD) is a well known process for depositing a binding matrix within a porous structure. The term "chemical vapor deposition" (CVD) generally implies deposition of a surface coating, but the term is also used to refer to infiltration and deposition of a matrix within a porous structure. As used herein, the term CVI/CVD is intended to refer to infiltration and deposition of a matrix within a porous structure. The technique is particularly suitable for fabricating high temperature structural composites by depositing a carbonaceous or ceramic matrix within a carbonaceous or ceramic porous structure resulting in very useful structures such as carbon/carbon aircraft
15 brake disks, and ceramic combustor or turbine components. The generally known CVI/CVD processes may be classified into four general categories: isothermal, thermal gradient, pressure gradient, and pulsed flow. See W.V. Kotlensky, Deposition of Pyrolytic Carbon in Porous Solids, 8 Chemistry and Physics of Carbon, 173, 190-203 (1973); W.J. Lackey, Review, Status, and Future of the Chemical Vapor Infiltration Process for Fabrication of Fiber-Reinforced Ceramic Composites, Ceram. Eng. Sci. Proc. 10[7-8] 577, 577-81 (1989) (W.J. Lackey refers to the pressure gradient process as "isothermal forced flow"). In an isothermal CVI/CVD process, a reactant gas passes around a heated porous structure at absolute pressures as low as a few millitorr. The gas diffuses into the porous structure driven by concentration gradients and cracks to deposit a binding matrix. This process is also known as "conventional" CVI/CVD. The porous structure is heated to a more or less uniform temperature, hence the term "isothermal," but this is actually a misnomer. Some variations in temperature within the porous structure are inevitable due to uneven heating (essentially unavoidable in most
20 furnaces), cooling of some portions due to reactant gas flow, and heating or cooling of other portions due to heat of reaction effects. In essence, "isothermal" means that there is no attempt to induce a thermal gradient that preferentially affects deposition of a binding matrix. This process is well suited for simultaneously densifying large quantities of porous articles and is particularly suited for making carbon/carbon brake disks. With appropriate processing conditions, a matrix with desirable physical properties can be deposited. However, conventional CVI/CVD may require weeks of
25 continual processing in order to achieve a useful density, and the surface tends to densify first resulting in "seal-coating" that prevents further infiltration of reactant gas into inner regions of the porous structure. Thus, this technique generally requires several surface machining operations that interrupt the densification process.

In a thermal gradient CVI/CVD process, a porous structure is heated in a manner that generates steep thermal gradients that induce deposition in a desired portion of the porous structure. The thermal gradients may be induced by
35 heating only one surface of a porous structure, for example by placing a porous structure surface against a susceptor wall, and may be enhanced by cooling an opposing surface, for example by placing the opposing surface of the porous structure against a liquid cooled wall. Deposition of the binding matrix progresses from the hot surface to the cold surface. The fixturing for a thermal gradient process tends to be complex, expensive, and difficult to implement for densifying relatively large quantities of porous structures.

40 In a pressure gradient CVI/CVD process, the reactant gas is forced to flow through the porous structure by inducing a pressure gradient from one surface of the porous structure to an opposing surface of the porous structure. Flow rate of the reactant gas is greatly increased relative to the isothermal and thermal gradient processes which results in increased deposition rate of the binding matrix. This process is also known as "forced-flow" CVI/CVD. Prior fixturing for pressure gradient CVI/CVD tends to be complex, expensive, and difficult to implement for densifying large quantities of
45 porous structures. An example of a process that generates a longitudinal pressure gradient along the lengths of a bundle of unidirectional fibers is provided in S. Kamura, N. Takase, S. Kasuya, and E. Yasuda, Fracture Behaviour of C Fiber/CVD C Composite, Carbon '80 (German Ceramic Society) (1980). An example of a process that develops a pure radial pressure gradient for densifying an annular porous wall is provided in United States Patents 4,212,906 and 4,134,360. The annular porous wall disclosed by these patents may be formed from a multitude of stacked annular
50 disks (for making brake disks) or as a unitary tubular structure. For thick-walled structural composites, a pure radial pressure gradient process generates a very large, undesirable density gradient from the inside cylindrical surface to the outside cylindrical surface of the annular porous wall. Also, the surface subjected to the high pressure tends to densify very rapidly causing that surface to seal and prevent infiltration of the reactant gas to low density regions. This behavior seriously limits the utility of the pure radial pressure gradient process.

55 Finally, pulsed flow involves rapidly and cyclically filling and evacuating a chamber containing the heated porous structure with the reactant gas. The cyclical action forces the reactant gas to infiltrate the porous structure and also forces removal of the cracked reactant gas by-products from the porous structure. The equipment to implement such a process is complex, expensive, and difficult to maintain. This process is very difficult to implement for densifying large

numbers of porous structures.

Many workers in the art have combined the thermal gradient and pressure gradient processes resulting in a "thermal gradient-forced flow" process. Combining the processes appears to overcome the shortcomings of each of the individual processes and results in very rapid densification of porous structures. However, combining the processes also results in twice the complexity since fixturing and equipment must be provided to induce both thermal and pressure gradients with some degree of control. A process for densifying small disks and tubes according to a thermal gradient-forced flow process is disclosed by United States Patent 4,580,524; and by A.J. Caputo and W.J. Lackey, Fabrication of Fiber-Reinforced Ceramic Composites by Chemical Vapor Infiltration, Prepared by the OAK RIDGE NATIONAL LABORATORY for the U.S. DEPARTMENT OF ENERGY under Contract No. DE-AD05-84OR21400 (1984). According to this process, a fibrous preform is disposed within a water cooled jacket. The top of the preform is heated and a gas is forced to flow through the preform to the heated portion where it cracks and deposits a matrix. A process for depositing a matrix within a tubular porous structure is disclosed by United States Patent 4,895,108. According to this process, the outer cylindrical surface of the tubular porous structure is heated and the inner cylindrical surface is cooled by a water jacket. The reactant gas is introduced to the inner cylindrical surface. Similar forced flow-thermal gradient processes for forming various articles are disclosed by T. Hunh, C.V. Burkland, and B. Bustamante, Densification of a Thick Disk Preform with Silicon Carbide Matrix by a CVI Process, Ceram. Eng. Sci. Proc 12[9-10] pp. 2005-2014 (1991); T.M. Besmann, R.A. Lowden, D.P. Stinton, and T.L. Starr, A Method for Rapid Chemical Vapor Infiltration of Ceramic Composites, Journal De Physique, Colloque C5, supplement au n°5, Tome 50 (1989); T.D. Gulden, J.L. Kase, and K.P. Norton, Forced-Flow Thermal-Gradient Chemical Vapor Infiltration (CVI) of Ceramic Matrix Composites, Proc.-Electrochemical Society (1990), 90-12 (Proc. Int. Conf. Chem. Vap. Deposition, 11th, 1990) 546-52. Each of these disclosures describes processes for densifying only one porous article at a time, which is impractical for simultaneously processing large numbers of composite articles such as carbon/carbon brake disks.

In spite of these advances, a CVI/CVD process and an apparatus for implementing that process are desired that rapidly and uniformly densifies porous structures while minimizing cost and complexity. Such a process would preferably be capable of simultaneously densifying large numbers (as many as hundreds) of individual porous structures. In particular, a process is desired for rapidly and economically densifying large numbers of annular fibrous preform structures for aircraft brake disks having desirable physical properties.

Summary of the Invention

According to an aspect of the invention, a CVI/CVD process is provided, comprising the steps of:

partially densifying a porous structure within a CVI/CVD furnace by depositing a first matrix within the porous structure with a pressure gradient CVI/CVD process in which a first portion of the porous structure is subjected to a greater pressure than a second portion of the porous structure and the first portion has a greater bulk density gain than the second portion; and, subsequently densifying the porous structure by depositing a second matrix within the porous structure with at least one additional densification process in which the second portion has a greater bulk density gain than the first portion.

According to another aspect of the invention, a CVI/CVD process is provided, comprising the steps of:

partially densifying a multitude of annular fibrous carbon structures within a CVI/CVD furnace by depositing a first carbon matrix within the annular fibrous carbon structure with a pressure gradient CVI/CVD process in which a first portion of each annular fibrous carbon structure is subjected to a greater pressure than a second portion of each annular fibrous carbon structure and the first portion has a greater bulk density gain than the second portion; and, subsequently densifying the multitude of annular fibrous carbon structures by depositing a second carbonaceous matrix within each annular fibrous carbon structure with at least one additional densification process in which the second portion has a greater bulk density gain than the first portion.

According to yet another aspect of the invention, a friction disk is provided, comprising:

a densified annular porous structure having a first carbon matrix deposited within the annular porous structure and a second carbon matrix deposited within the annular porous structure overlying the first carbon matrix, the densified annular porous structure having two generally parallel planar surfaces bounded by an inside circumferential surface and an outside circumferential surface spaced from and encircling the inside circumferential surface, a first circumferential portion adjacent the inside circumferential surface, and a second circumferential portion adjacent the outside circumferential surface, wherein the first and second circumferential portions are bounded by the two

generally parallel planar surfaces, the second circumferential portion having at least 10% less of the first carbon matrix per unit volume relative to the first circumferential portion, the first carbon matrix and the second carbon matrix having a substantially rough laminar microstructure, and the first carbon matrix being more graphitized than the second carbon matrix.

According to still another aspect of the invention, a CVI/CVD process in a CVI/CVD furnace is provided, comprising the steps of:

introducing a reactant gas into a sealed preheater disposed within the CVI/CVD furnace, the sealed preheater having a preheater inlet and a preheater outlet, the reactant gas being introduced into the preheater inlet and exiting the sealed preheater through the preheater outlet and infiltrating at least one porous structure disposed within the CVI/CVD furnace;

heating the at least one porous structure;

heating the sealed preheater to a preheater temperature greater than the reactant gas temperature;

sensing a gas temperature of the reactant gas proximate the outlet;

adjusting the preheater temperature to achieve a desired gas temperature; and,

exhausting the reactant gas from the CVI/CVD furnace.

According to still another aspect of the invention, an apparatus is provided for introducing a first reactant gas into a CVI/CVD furnace, comprising:

a first main gas line for supplying the first reactant gas;

a plurality of furnace supply lines in fluid communication with the first main gas line and the CVI/CVD furnace;

a plurality of first flow meters that measure a quantity of first reactant gas flow through each furnace supply line;

and,

a plurality of first control valves configured to control the quantity of flow of the first reactant gas through each furnace supply line.

According to still another aspect of the invention, a CVI/CVD densification process is provided, comprising the steps of:

densifying a first porous wall within a CVI/CVD furnace by a pressure gradient CVI/CVD process wherein a first flow of reactant gas is forced to disperse through the first porous wall;

densifying a second porous wall by a pressure gradient CVI/CVD process wherein a second flow of reactant gas is forced to disperse through the second porous wall; and,

independently controlling the first flow of the reactant gas and the second flow of the reactant gas.

Brief Description of the Drawings

Detailed Description of the Invention

20 The invention and various embodiments thereof are presented in Figures 1 through 29 and the accompanying descriptions wherein like numbered items are identical. As used herein, the term "conventional CVI/CVD" is intended to refer to the previously described isothermal CVI/CVD process. The term "pressure gradient CVI/CVD" is intended to refer to the previously described pressure gradient CVI/CVD or forced-flow process and is intended to specifically exclude the previously described thermal gradient and thermal gradient-forced flow processes to the extent that these processes utilize an intentionally induced thermal gradient that affects the deposition process.

25 Referring now to Figure 1, a schematic depiction is presented of a CVI/CVD furnace 10 adapted to deposit a matrix within a porous structure 22 by a pressure gradient CVI/CVD process according to an aspect of the invention. The furnace 10 has a shell 13 with an inner surface 12 that defines a furnace volume 14, and a gas inlet 16 for introducing a gas into the furnace 10. A susceptor 30 is disposed around the reactor volume 35 and is induction heated by an induction coil 20 according to methods well known in the art. Other methods of heating may also be utilized such as resistance heating and microwave heating, any of which are considered to fall within the purview of the invention. An insulation barrier 31 is disposed between the susceptor 30 and the induction coil 20. The susceptor 30 has an inner surface 33 that defines a reactor volume 35 which is included within the furnace volume 14. The porous structure 22 is disposed within a fixture 2 in the reactor volume 35 and is predominantly heated by radiation from the susceptor 30. A vacuum apparatus 58 comprising a vacuum pump or steam vacuum system is in fluid communication with an exhaust 32 and evacuates the furnace volume 14 to a pressure below atmospheric pressure. A reactant gas is introduced into the reactor volume 35 through the gas inlet 16 that receives the reactant gas from a furnace supply line 26. The reactant gas infiltrates the porous structure 22 where it cracks and deposits a matrix within the porous structure 22. A single type of gas or mixtures of multiple types of gases may be supplied to the gas inlet 16.

40 According to a preferred embodiment, the reactant gas comprises a mixture of two reactant gases that are introduced through a first main gas line 42 and a second main gas line 44. The furnace supply line 26 is in fluid communication with the first and second main gas lines 42 and 44 and the inlet 16 thereby serving to transfer the reactant gases to the furnace 10. A first flow meter 46 measures the quantity of flow of a first gas (indicated by arrow 50) introduced into the furnace supply line 26 through the first main supply line 42, and a second flow meter 48 measures the quantity of flow of a second gas (indicated by arrow 52) introduced into the furnace supply line 26 through the second main gas line 44. The flow of gas into furnace supply line 26 is controlled by a first control valve 54 which controls the flow of the first reactant gas from the first main gas line 42, and by a second control valve 56 which controls the flow of the second reactant gas from the second main gas line 44.

50 The porous structure 22 includes a porous structure aperture 23. A tube 60 is in fluid communication with fixture 2 and the inlet 16 thereby serving to transfer the reactant gas to the fixture 2. The fixture 2 comprises a pair of plates 38 and 40, and the tube 60 is sealed to the gas inlet 16 and to the plate 38. The porous structure 22 is sealed between the plates by ring-like spacers 62 and 64, and the plates 38 and 40 are held together by tie-rods 66. The porous structure 22 forms a porous wall 68 disposed between the inlet 16 and the exhaust 32. The furnace volume 14 and reactor volume 35 are reduced to a pressure below atmospheric pressure, and the gas is introduced to the porous structure aperture 23 at a greater pressure than the reactor volume pressure which develops a pressure gradient through the porous wall 68 and forces dispersion of the gas through porous structure 22 before being withdrawn from the reactor volume 35 and the furnace volume 14 by the vacuum apparatus 58 as indicated by arrows 34, 36, and 28.

Pressure inside the furnace volume is measured by an exhaust pressure sensor 72, and pressure inside the porous

structure aperture 23 is measured by an inlet pressure sensor 70. An approximate reactant gas temperature inside the porous structure aperture 23 is measured by a flow temperature sensor 74, and porous structure temperature is approximated by a structure temperature sensor 76 which is placed in close proximity to the plate 40. As will be discussed in more detail, the temperature and pressure conditions are chosen to cause the gas to crack and deposit a matrix having certain desired properties within the porous structure 22. The various aspects of the invention may be used to deposit any type of CVI/CVD deposited matrix including, but not limited to, carbon or ceramic matrix deposited within carbon or ceramic based porous structures 22. The invention is particularly useful for depositing a carbon matrix within a carbon-based porous structure, and especially for making carbon/carbon composite structures such as aircraft brake disks.

Referring now to Figure 2, a detailed view of the fixture 2 for holding porous structure 22 is presented. According to a preferred embodiment, the porous structure is annular and has two opposing generally planar surfaces 78 and 80 that are bounded by an inside circumferential surface 82 and an outside circumferential surface 84. An "OD" (outside diameter) type ring-like spacer 64 having a mean diameter less than the outside circumferential surface 84 is placed between the porous structure 22 and the plate 38. An "ID" (inside diameter) type ring-like spacer 62 having a mean diameter slightly greater than the inside circumferential surface 82 is placed between the porous structure 22 and the plate 40. The ring-like spacers 62 and 64 also serve as spacers to permit gas flow between porous structure 22 and the plates 38 and 40, and also seal the porous structure 22 to the plates 38 and 40. The tie-rods 66 may be threaded on one or both ends and include nuts 67 in threaded engagement. Washers 69 may be used to distribute the load to the plates 38 and 40.

As discussed previously, the furnace volume is subjected to a vacuum and reactant gas is introduced into the tube 60 at a greater pressure than the furnace volume. Thus, a first portion 86 (indicated by fine crosshatching) of the fibrous structure 22 is subjected to a greater pressure than a second portion 88 (indicated by fine crosshatching) of the fibrous structure 22 which induces dispersion of the reactant gas through the porous structure 22 as indicated by the arrows 90. As gas disperses through the porous structure, additional gas flows through the tube 60 and toward the porous structure 22 as indicated by arrows 92. Thus, reactant gas is continuously supplied and forced to disperse through the porous structure 22. In this example, the first portion 86 includes one surface 78 of the two opposing surfaces 78 and 80, and the second portion 88 includes the other surface 80 of the two opposing surfaces 78 and 80. The first portion 86 also includes the inside circumferential surface 82, and the second portion 88 includes the outside circumferential surface 84.

Referring now to Figure 3, an alternative fixture 4 that may be used in place of fixture 2 is depicted wherein two porous structures 22 are stacked and simultaneously densified. Two ring-like spacers 64 are utilized and tie-rods 66 are longer versions of the tie-rods 66 of Figure 2. A pressure gradient is applied to the porous structure (as previously described in relation to Figure 2) resulting in dispersion of the reactant gas through the porous structures 22 as indicated by arrows 90. Other features of fixture 4 are identical to fixture 2.

The reactant gas tends to crack and preferentially deposit the matrix within the portions of the porous structure 22 subjected to a pressure relatively greater than the pressure in other portions. For example, Figure 8 presents a densified structure 300 that results from the Figure 2 and 3 processes beginning with a porous structure 22. The degree of crosshatching is intended to generally indicate relative density: finely crosshatched areas represent greater density relative to coarsely crosshatched areas. The density monotonically decreases from a greatest density zone 302 to a least density zone 308 with density zones 304 and 306 representing intermediate density ranges. The densified structure 300 has an average bulk density, and density zone 302 is typically 110%-140% of the average bulk density, and density zone 308 is typically 60%-90% of the average bulk density. Note that the highest density zone 302 generally corresponds to the first portion 86 and the lowest density zone 308 generally corresponds to the second portion 88. Thus, the first portion 86 has a greater bulk density gain than the second portion 88 during the pressure gradient CVI/CVD process depicted in Figures 2 and 3.

The density gradient depicted in Figure 8 is unacceptable for many applications. The density gradient may be reduced by depositing a first matrix within the porous structure with a pressure gradient CVI/CVD process, as shown in Figures 2 and 3. In this first process, the first portion 86 has a greater bulk density gain than the second portion 88, as shown in Figure 8. Subsequently, the porous structure 22 may be further densified by depositing a second matrix with at least one additional densification process in which the second portion 88 has a greater bulk density gain than the first portion 86. For example, the partially densified structure 300 of Figure 8 could be flipped and subjected to the pressure gradient CVI/CVD process depicted in Figures 2 and 3. The second portion 88 is subjected to a greater pressure than the first portion 86, which results in the second portion 88 having a greater bulk density gain than the first portion 86. Figure 9 depicts a densified structure 310 resulting from this two-step/flip process. The density monotonically decreases from a greatest density zone 312 to a least density zone 316 with density zone 314 representing an intermediate density range. The densified structure 310 has an average bulk density, and density zone 312 is typically 105%-115% of the average bulk density, and density zone 316 is typically 85%-95% of the average bulk density. The density gradient is now generally symmetrical through the thickness of the porous structure 22 which is desirable for brake disk

applications. The density gradient is also less than the density gradient of the densified structure 300 depicted in Figure 8. The second or additional densification processes may include pressure gradient CVI/CVD, conventional CVI/CVD, and resin impregnation followed by charring. In addition, a porous structure partially densified with a carbon matrix may be heat treated at a temperature greater than the processing temperatures of previous CVI/CVD processes to increase graphitization of the carbon matrix before further depositing additional matrix.

Referring now to Figure 4, another alternative fixture 6 that may be used in place of fixture 2 for an alternative pressure gradient CVI/CVD process is presented. The fixture 6 utilizes all "ID" ring-like spacers 62 resulting in only the inner circumferential surface 82 of each porous structure being subjected to a greater pressure than the reactor volume 35. Thus, a first portion 87 of porous structure 22 is subjected to a greater pressure than a second portion 89 resulting in pressure driven flow of the reactant gas through the porous structures 22 as indicated by arrows 91. In this example, the first portion 87 includes the inside circumferential surface 82, and the second portion 89 includes the outside circumferential surface 84 and two opposing surfaces 78 and 80. The reactant gas tends to quickly flow through the porous structure 22 and exit near the ring-like spacer 62. Thus, reactant gas is not forced to disperse through all of the porous structure 22. Figure 10 presents a densified structure 320 generated by the Figure 4 process. The densified structure 320 comprises a zone 322 of greatest density adjacent the inside circumferential surface 82 which drops off to a zone 328 of least density at the core. The density monotonically increases from the least density zone 328 to the greatest density zone 322 with density zones 324 and 326 representing intermediate density ranges. The densified structure 320 has an average bulk density, and density zone 322 is typically about 140% of the average bulk density, and density zone 324 is typically about 115% of the average bulk density. Density zone 328 is typically about 80% of the average bulk density. The zone 322 of greatest density generally corresponds with the first portion 87 of Figure 4. The region of intermediate density 324 adjacent the outside circumferential surface 320 is generated by a conventional CVI/CVD process induced by reactant gas flow that has not fully cracked exhausting from adjacent porous structures. The densified structure 320 may be further densified by second or additional densification processes which include pressure gradient CVI/CVD, conventional CVI/CVD, and resin impregnation followed by charring.

Referring now to Figure 5, an alternative fixture 8 that may be used in place of fixture 2 for an alternative pressure gradient CVI/CVD process is presented. The fixture 8 utilizes all "OD" ring-like spacers 64 resulting in the inside circumferential surface 82 and the opposing surfaces 78 and 80 of each porous structure being subjected to a greater pressure than reactor volume 35. The outside circumferential surface 84 is subjected to the pressure of the reactor volume 35. Thus, a first portion 94 of porous structure 22 is subjected to a greater pressure than a second portion 96 resulting in pressure driven flow of the reactant gas through the porous structures 22 as indicated by arrows 98. In this example, the first portion 94 includes the inside circumferential surface 82 and the opposing surfaces 78 and 80, and the second portion 96 includes the outside circumferential surface 84. As depicted, the reactant gas is forced to disperse through all of the porous structure 22. Figure 11 presents a densified structure 330 generated by the Figure 5 process. The densified structure 330 comprises a zone 332 of greatest density adjacent the inside circumferential surface 82 and part of the two opposing surfaces 78 and 80. The zone 332 sometimes extends all the way to the outside circumferential surface 84 and includes essentially all of the opposing surfaces 78 and 80. The density monotonically decreases from the greatest density zone 332 to a least density zone 338 with density zones 334 and 336 representing intermediate density ranges. The densified structure 330 has an average bulk density, and density zone 332 is typically 110%-125% of the average bulk density, and density zone 338 is typically 80%-90% of the average bulk density. The Figure 5 process generates a densified structure 330 that has a symmetric density gradient through the structure thickness. However, the density gradient may be skewed toward one of the surfaces 78 or 80 in some densified structures 330 due to process variations. Note that the zones 332 and 334 generally correspond to the first portion 94 of Figure 5, and the second portion 96 experiences a relatively less bulk density gain as indicated by zones 336 and 338. The densified structure 330 may be further densified by second or additional densification processes which may comprise pressure gradient CVI/CVD, conventional CVI/CVD, or resin impregnation followed by charring.

Referring now to Figure 12, a densified structure 340 is presented that is generated by further densifying the porous structure 330 of Figure 11 by a conventional CVI/CVD process. As shown, the greatest density appears in a zone 342 adjacent the inside circumferential surface 82, which is residual from zone 332 of Figure 11. The subsequent conventional CVI/CVD process decreases the radial density gradient. This is indicated by a zone 344 of intermediate density adjacent the outside circumferential surface 84. A zone of lesser density 346 encircles a core zone 348 of least density. The subsequent process fills the lower density portions remaining in the densified structure 330 of Figure 11. Thus, the second portion 96 from the Figure 5 process experiences a greater bulk density gain than the first portion 94 during the subsequent conventional CVI/CVD process. In addition, the pressure gradient CVI/CVD process generated by the Figure 5 process produces a desirable porosity distribution in densified structure 330 that renders structure 330 extremely susceptible to subsequent densification by conventional CVI/CVD processes. Densified structure 330 reaches final density quicker and has minimal tendency to seal-coat during subsequent conventional CVI/CVD processes than a structure having the same bulk density that was previously densified by only conventional CVI/CVD processes. This greatly minimizes the need for surface machining operations during the subsequent processes, which greatly simplifies

and expedites the entire densification process. This synergistic effect was a surprising discovery.

Referring now to Figure 6, an alternative fixture 9 that may be used in place of fixture 2 for an alternative pressure gradient CVI/CVD process is presented. The process presented in Figure 6 is a "reverse flow" process wherein the reactant gas enters the porous structure 22 from the outside rather than the inside of the porous structure 22. This is accomplished by disposing the porous structure 22 between plates 38 and 41. Plate 41 is essentially identical to plate 40 except that plate 41 includes an aperture 43. A cylindrical barrier structure 350 is disposed between and sealed to plates 38 and 41. The barrier structure 350 encircles the porous structure 22. The outside diameter of surface 80 is spaced from and sealed to the plate 41 by an "OD" ring-like spacer 64. The outside diameter of surface 78 is spaced from and sealed by an "OD" ring-like spacer 64 to a seal plate 352, which is disposed between the porous structure 22 and plate 38. A plurality of spacing blocks 353 space the seal plate 352 from the plate 38 thereby forming a plurality of apertures 354. Reactant gas is introduced into fixture 9 the direction of arrow 92. The seal plate 352 forces the gas to flow radially outward and through the apertures 354. The barrier structure 350 then forces the gas to flow upward as indicated by arrows 356 toward the outside circumferential surface 84 of porous structure 22. The aperture 43 in plate 41 subjects the inside of the fixture to the furnace volume pressure which is less than the gas supply pressure in tube 60. Thus, a first portion 95 is subjected to a greater pressure than a second portion 97 which forces the gas to disperse through the porous structure 22 as indicated by arrows 99. The gas exhausts from fixture 9 to the reactor volume 35 through the aperture 43 as indicated by arrow 358. In this example, the first portion 95 includes the outside circumferential surface 84, and the second portion 97 includes the inside circumferential surface 82 and the opposing surfaces 78 and 80. The densified structure may be further densified by second or additional densification processes including pressure gradient CVI/CVD, conventional CVI/CVD, or resin impregnation followed by charring.

Referring now to Figure 7, an alternative fixture 7 that may be used in place of fixture 2 for an alternative pressure gradient CVI/CVD process is presented. Figure 7 presents a reverse flow process which is very similar to the Figure 6 process. Fixture 7 is essentially identical to fixture 9, except that fixture 7 comprises "ID" ring-like spacers 62 rather than "OD" ring like spacers 64. The flow of reactant gas enters the opposing surfaces 78 and 80 and the outside circumferential surface 84, and exits the inside circumferential surface 82 of porous structure 22 as indicated by arrows 101. The inside circumferential surface 82 is subjected to the pressure of the reactor volume 35, and the outside circumferential surface 84 and the opposing surfaces 78 and 80 are subjected to the reactant gas supply pressure. Thus, a first portion 552 of porous structure 22 is subjected to a greater pressure than a second portion 550. In this example, the first portion 552 includes the inside circumferential surface 82, and the second portion 550 includes the outside circumferential surface 84 and the opposing surface 78 and 80. Figure 13 presents a densified structure 341 generated by the Figure 7 process. The densified structure 341 comprises a zone 343 of greatest density adjacent the outside circumferential surface 84 and part of the two opposing surfaces 78 and 80. The density monotonically decreases from the greatest density zone 343 to a least density zone 349 with density zones 345 and 347 representing intermediate density ranges. The densified structure 341 has an average bulk density, and density zone 343 is typically about 120% of the average bulk density, and density zone 349 is typically about 80% of the average bulk density. The densified structure 341 may be further densified by second or additional densification processes including pressure gradient CVI/CVD, conventional CVI/CVD, or resin impregnation followed by charring.

The various components of fixtures 2, 4, 6, 7, 8 and 9 are preferably formed from graphite, but any suitable high temperature resistant material may be used in the practice of the invention. The various joints may be sealed using compliant gaskets and/or liquid adhesives such as a graphite cement. The porous structures may be pressed against the ring-like spacers to form appropriate seals if the porous structures are compliant before densification. Suitable compliant gaskets may be formed from a flexible graphite such as EGC Thermafol® brand flexible graphite sheet and ribbon-pack available from EGC Enterprises Incorporated, Mentor, Ohio, U.S.A. Comparable materials are available from UCAR Carbon Company Inc., Cleveland, Ohio, U.S.A.

A conventional CVI/CVD process may be carried out using a CVI/CVD furnace 11 as depicted in Figure 14. Furnace 11 is very similar to Furnace 10 (see Figure 1). However the fixture 2 is eliminated and replaced with a fixture 360. Fixture 360 comprises a support plate 362 disposed on a plurality of support posts 364. The porous structure is disposed on a plurality of spacers 368 that separate the porous structure 22 from the plate 362 permitting dispersion of the reactant gas between the plate 362 and the porous structure 22. The support plate 362 has a multitude of perforations (not shown) to permit dispersion of reactant gas through the plate and around the porous structure 22. The support posts 364, spacers 368, and perforated support plate 362 are preferably formed from graphite. Tube 60 of Figure 1 is replaced by a larger diameter tube 366. Gas enters the furnace volume and freely expands as indicated by arrows 370. The gas passes over the porous structure as indicated by arrows 34 and exhausts from the furnace volume 14 to the vacuum device 58 as indicated by arrows 36 and 28. Normally, only one temperature sensor 76 is used which generally senses the temperature of porous structure 22. The pressure measured by pressure sensor 70 is only slightly greater than the pressure measured by pressure sensor 72 during a conventional CVI/CVD process. A mixture of reactant gases may be introduced from main supply lines 42 and 44, as previously described in relation to Figure 1.

With each of the Figure 2 through Figure 7 fixtures, each annular porous structure 22 has a surface area with a

majority (more than 50%) of the surface area of each annular porous structure being exposed to the reactant gas as it enters or leaves the porous structure 22. Establishing a high level of exposure reduces the pressure gradient required to force dispersion of the gas through each porous structure. As much of the porous structure surface area as possible is preferably exposed to the reactant gas. Preferably, at least 80% of the porous structure surface area is exposed.

5 Referring now to Figure 15, a CVI/CVD furnace 400 and an apparatus 402 for introducing a first reactant gas into the furnace 400 is presented. Furnace 400 and apparatus 402 are particularly suited for simultaneously densifying large quantities of porous articles, for example five hundred to one thousand annular preforms for manufacturing aircraft brake disks. A first main gas line 404 supplies the first reactant gas as indicated by arrow 406. A plurality of furnace supply lines 408 are in fluid communication with the first main gas line 404 and the CVI/CVD furnace 400. A plurality of
10 first flow meters 410 measures a quantity of first reactant gas flow through each furnace supply line 408. A plurality of first control valves 412 are configured to control the quantity of flow of the first reactant gas through each furnace supply line 408. Apparatus 402 comprises four supply lines 408, four control valves 412, and four flow meters 410, but the invention is not limited to four of each component, since the number may be increased or decreased as required.

According to a preferred embodiment, the furnace 400 and reactant gas supply apparatus 402 are controlled by a
15 controller 414. Each flow meter 410 may communicate the measured quantity of flow to the controller 414 via a first flow sensor line 416, and the controller 414 may control each control valve 412 via a first valve control line 418. Thus, the quantity of flow of the first reactant gas into the furnace 400 may be independently set and controlled for each supply line 408. The controller 414 is preferably micro-processor based and comprises a screen 415 for monitoring the various conditions and control states in the reactant gas supply apparatus 402 and the furnace 400. According to a certain
20 embodiment, each furnace supply line 408 comprises one first flow meter 410 and one first control valve 412, as shown in Figure 15, and a first main control valve 420 disposed within the first main gas line 404. The first main control valve 420 preferably controls pressure in the first main gas line 404. A first main flow meter 422 may also be disposed within the first main gas line 404.

A mixture of gases may be supplied to furnace 400 by providing at least a second main gas supply line 424 for supplying a second reactant gas as indicated by arrow 426. A plurality of second flow meters 430 are provided that measure a quantity of second reactant gas flow through each furnace supply line 408 with a plurality of second control valves 432 configured to control the quantity of flow of the second reactant gas through each furnace supply line 408. Each
25 second flow meter 430 may communicate the measured quantity of flow to the controller 414 via a second flow sensor line 436, and the controller 414 may control each second control valve 432 via a second valve control line 438. According to a certain embodiment, the second main gas line 424 comprises a second main control valve 440 disposed within the second main gas line 424. A second main flow meter 442 may also be disposed within the second main gas line 424. The second main control valve 440 preferably controls pressure in the second main gas line 424.

The furnace 400 comprises a furnace shell 444 that defines a furnace volume 446. A reactor volume 447 is included within the furnace volume 446. The furnace supply lines 408 are in fluid communication with the reactor volume 447. A vacuum apparatus 448 is in fluid communication with the furnace volume 446 and reactor volume 447 via
35 exhaust stacks 450. The vacuum apparatus 448 reduces the pressure in furnace volume 446 to a vacuum pressure (below atmospheric) and may comprise any suitable device such as a vacuum pump or steam vacuum system with appropriate filters and scrubbers that remove undesirable by-products from the spent reactant gas. The reactant gas from a given furnace supply line 408 is introduced into a corresponding preheater 458. A first preheater 458 is disposed
40 within the reactor volume 447 and has an inlet 460 and an outlet 461. The first preheater 458 is sealed such that substantially all of the reactant gas introduced into the inlet 460 from a corresponding furnace supply line 408 is heated and leaves the preheater through the corresponding outlet 461 where it infiltrates at least one porous structure disposed within the furnace. The term "substantially all of the gas" is intended to allow for a small amount of leakage. The first preheater 458 is heated to a preheater temperature greater than the reactant gas temperature from the corresponding
45 furnace supply line 408. The porous structure is also heated. In this example the porous structure comprises a first porous wall 452 disposed within the reactor volume 447. The first porous wall 452 is preferably annular and comprises a first top plate 454 that seals the upper open end of the first porous wall 452, thereby defining a first enclosed cavity 456. The other end of the first porous wall 452 is sealed against the first preheater 458, with the first preheater outlet 461 in fluid communication with the first enclosed cavity 456.

50 A first flow of reactant gas is introduced into the first preheater 458, and then passes into the first enclosed cavity 456 at a pressure greater than the pressure within the reactor volume 447. Thus, one side of the first porous wall 452 is subjected to a greater reactant gas pressure than the other side of the first porous wall. In the example shown in Figure 15, the inner side of the porous wall 452 (the enclosed cavity 456) is subjected to a greater reactant gas pressure than the outer side of porous wall 452. The pressure difference forces the first flow of reactant gas to disperse through
55 the first porous wall 452 where the heated gas cracks and deposits a binding matrix within the heated first porous wall 452. The remaining gas and any by-products then exit the first porous wall 452 and are exhausted from the reactor volume 447 through exhaust stacks 450 by vacuum apparatus 448. Thus, the reactant gas is forced to disperse through the annular porous wall by introducing the reactant gas to the CVI/CVD furnace and exhausting the reactant gas from

the CVI/CVD furnace on opposite sides of the annular porous wall. At least one exhaust stack 450 is preferably provided between each pair of porous walls. Also, each preheater 458 may supply reactant gas to more than one annular porous wall 452. Furnace 400 may be heated by any method known in the art for heating a CVI/CVD furnace, including resistance heating and induction heating.

5 According to a preferred embodiment, the preheater 458 and porous wall 452 are radiation heated by a susceptor 462 that encloses the first preheater 458 and porous wall 452 on all sides. The susceptor 462 defines the reactor volume 447 and a floor 463 upon which the first preheater 458 rests. The susceptor 462 preferably comprises a circumferential portion 464 and the furnace 400 comprises a first induction coil 466, a second induction coil 468, and a third induction coil 470 that encircle the circumferential portion 464. The susceptor 462 is inductively coupled with the induction coils 466, 468, and 470 which transfer energy to the susceptor 462, where it is transformed into heat in a manner well known in the art. Maintaining a uniform temperature from the bottom to the top of a CVI/CVD furnace during densification of a large number of porous structures (hundreds) may be difficult. The rate at which the gas cracks and deposits the binding matrix is largely determined by temperature assuming the reactant gas concentration is sufficient. Thus, variations in porous structure temperature throughout the furnace cause corresponding variations in bulk density gain which can reduce yield during a given CVI/CVD run. Incorporating multiple induction coils, as depicted in Figure 15, permits application of differing amounts of heat along the length of the furnace. A more uniform porous structure temperature profile along the length of the furnace (in direction of gas flow) may thus be obtained.

According to a further embodiment, a first gas temperature of the first flow of reactant gas is sensed proximate the first preheater outlet 461 by a first temperature sensor 490. Temperature sensor 490 may comprise a Type K thermocouple with appropriate protective sheathing. The preheater temperature may be adjusted to achieve a desired gas temperature. Measuring the preheater temperature directly is not necessary since the preheater temperature is convectively related to the gas temperature at the outlet 461. The preheater temperature is adjusted by increasing or decreasing the heating of the first preheater 458. In Figure 15, the susceptor wall 464 is comprised of a first susceptor wall portion 467, a second susceptor wall portion 469, and a third susceptor wall portion 471. As previously described, the first induction coil 466 is inductively coupled to the first susceptor wall portion 467 in a manner that transforms electrical energy from the first induction coil 466 to heat energy in the first susceptor wall portion 467. The same applies to the second susceptor wall portion 469 and the second induction coil 468, and the third susceptor wall portion 471 and third induction coil 470. The first preheater 458 is predominantly heated by radiation heat energy from the first susceptor wall portion 467 which is adjacent the first induction coil 466. Thus, the first preheater temperature may be adjusted by adjusting electrical power to the first induction coil 466. The electrical power to the second induction coil 468 and 470 may be adjusted as necessary to maintain a desirable porous structure temperature profile along the length of the furnace. The first preheater 458 is preferably disposed proximate the first susceptor wall portion 467 which improves the transfer of heat energy by radiation. The temperature sensed by first temperature sensor 490 may be transmitted to the controller 414 via a first temperature sensor line 494. The controller may process the temperature sensor information and automatically adjust electrical power to the first induction coil 466 as necessary to achieve a desired temperature of the first gas flow as it leaves the first preheater outlet 461. In certain furnace arrangements, a preheater may be disposed proximate the center of the furnace and surrounded by adjacent preheaters that are proximate the susceptor wall and block transfer of heat energy by radiation to the center preheater. In such a case, the center preheater is heated predominantly by conduction from the adjacent preheaters that are heated by radiation. Thus, the center preheater is indirectly heated by radiation from the susceptor wall and the center preheater temperature may be controlled by varying power to the first induction coil 466. Also, the preheaters could be resistance heated which would permit direct control of the heat energy supplied to each preheater. Any such variations are considered to be within the purview of the invention.

A second porous wall 472 may be sealed to a second preheater 478 with the second porous wall having a second top plate 474. The second preheater 478 has a second preheater inlet 480 and a second preheater outlet 481. A second temperature sensor 492 may be provided for sensing the temperature of the second flow of reactant gas as it exits the second preheater outlet 481. The second porous wall 472 defines a second enclosed cavity 476 that is in fluid communication with the second preheater outlet 481. A second flow of gas is introduced to the second preheater through a corresponding furnace supply line 408 and is forced to disperse through the second porous wall 472 and exit the furnace volume 446 in the same manner as described in relation to the first porous wall 452. Thus, one side of the second porous wall 472 is subjected to a greater pressure than the other side of the second porous wall. According to a certain embodiment, the second preheater 478 and second porous wall 472 are heated predominantly by radiation from the susceptor wall 464. The second preheater 478 is heated to a preheater temperature greater than the reactant gas temperature from the corresponding furnace supply line 408. The heated gas infiltrates the second porous wall 472 where it cracks and deposits a binding matrix. The remaining gas and any by-products then exit the second porous wall 472 and are drawn out of the furnace volume 446 by vacuum apparatus 448. A second temperature sensor 492 may be provided proximate the second preheater outlet 481. The temperature sensed by second temperature sensor 492 may be transmitted to the controller 414 via a second temperature sensor line 496. The controller 414 may process the temper-

ature sensor information and automatically adjust electrical power to the first induction coil 466 as necessary to achieve a desired temperature of the second gas flow as it leaves the second preheater outlet 481. Electrical power to the first induction coil 466 may also be manually adjusted as necessary in order to achieve the desired gas flow temperature. At least a third porous wall may be densified by a similar pressure gradient CVI/CVD process wherein at least a third flow of reactant gas is forced to disperse through at least the third porous wall by subjecting one side of at least the third porous wall to a greater pressure than the other side of at least the third porous wall, and the third flow of gas may be independently controlled. Additional porous walls may be added and densified in an identical manner using additional furnace supply lines 408 and additional preheaters. Additional preheaters and temperature sensors for sensing temperature of the gas flow proximate the outlet of each additional preheater may be provided as required. Thus, the invention permits simultaneous densification of large numbers of porous walls.

A porous wall temperature sensor 498 may be provided in close proximity to the first porous wall 452 for sensing a first porous wall temperature. The first porous wall temperature may be increased or decreased by increasing or decreasing the first flow of reactant gas that passes through the first porous wall 452. For example, the first flow of reactant gas may be at a lesser temperature than the porous structure as it exits the first preheater outlet 481. Increasing the first flow of reactant gas at this lesser temperature tends to decrease the porous wall temperature and decreasing the flow tends to increase the porous wall temperature. The reverse would apply if the first flow of reactant gas was at a greater temperature than the first porous wall 452. The first porous wall temperature sensor 498 may communicate with the controller 414 via a first porous wall temperature sensor line 502 which permits automatic or manual control of the first gas flow as necessary to achieve a desired first porous wall temperature. A second porous wall temperature may be similarly sensed by a second porous wall temperature sensor 500. The second porous wall temperature sensor 500 may communicate with the controller 414 via a second porous wall temperature sensor line 504 which permits automatic or manual control of the second gas flow as necessary to achieve a desired second porous wall temperature by increasing or decreasing the second gas flow. Temperature of third and additional porous walls may be sensed and controlled in similar manner. Each individual flow of gas from the furnace supply lines 408 may be independently controlled in order to influence the CVI/CVD deposition process by virtue of the reactant gas supply apparatus 402. The porous wall temperature sensors may also be inserted directly in to the porous walls as indicated by temperature sensor 508. A thermocouple may be placed between an adjacent pair of annular porous structures if the porous wall is formed from a stack of porous structures. Porous wall temperature may also be sensed by an optical pyrometer 548 focused through a window 546 on an optical target 544 disposed between an adjacent pair of porous walls 452 and 472.

According to a preferred embodiment, the furnace volume 446 is maintained at a constant vacuum pressure. The pressure inside the first enclosed cavity 456, second enclosed cavity 476, and any third or additional enclosed cavities is determined by the flow of reactant gas introduced into that cavity and the porosity of the corresponding porous wall. For example, the flow into the first enclosed cavity 456 may be maintained at a constant value. At the beginning of the densification process, the pressure inside the first enclosed cavity may be only slightly higher than the furnace volume pressure outside the enclosed cavity. The pressure inside the first enclosed cavity 456 increases as matrix is deposited within the first porous wall 452 because porosity decreases and the quantity of first flow of reactant gas is constant. The pressure inside the first enclosed cavity 456 may be controlled by increasing or decreasing the flow of reactant gas into the first enclosed cavity. Increasing flow increases pressure and decreasing the flow decreases pressure. A first pressure sensor 508 may be provided for sensing the pressure inside the first enclosed cavity 456. The first pressure sensor 508 may communicate via first pressure sensor line 512 with the controller 414 which allows automatic or manual control of the quantity of flow introduced into the first enclosed cavity 456 as necessary to achieve a desired pressure. A second pressure sensor 510 and second pressure sensor line 514 may be provided for controlling the flow and pressure inside the second enclosed cavity 476 in like manner. Third and additional pressure sensors and pressure sensor lines may be provided as required. The quantity of gas flow into a given enclosed cavity is preferably fixed and the pressure allowed to naturally rise as the porous wall densifies unless the pressure rises too rapidly or exceeds a maximum desired pressure, in which case the flow may be reduced or completely stopped. The reactant gas supply apparatus 402 allows independent control of the flow to each porous wall. Monitoring the pressure inside the porous cavity also provides a real time indication of the degree of densification of each porous wall. The lack of a pressure rise, or an unusually slow pressure rise, indicates the presence of a leak in the preheater and/or the porous wall. The process may be terminated and subsequently restarted once the leak is located and fixed. An unusually rapid pressure may indicate sooting or tarring of one or more of the annular porous walls.

Referring now to Figure 16, a preheater 100 is presented which is a preferred embodiment for the preheaters 458 and 478 of Figure 15. The preheater 100 is described in more detail in a copending United States patent application entitled APPARATUS FOR USE WITH CVI/CVD PROCESSES; filed the same day as the present application naming James W. Rudolph, Mark J. Purdy, and Lowell D. Bok as inventors, and which is fully incorporated herein by reference. The preheater 100 comprises a sealed duct structure 102 disposed within the furnace 10 and resting on the susceptor floor 463. The preheater 100 receives gas from the gas inlet 460 (Figure 15). The gas inlet 460 may be connected to one or more perforated tubes 19 which promote dispersion of the gas throughout the sealed duct structure 102. Pre-

heater 100 comprises a sealed baffle structure 108 that rests upon a sealed duct structure 102. The sealed baffle structure 108 comprises an array of spaced perforated plates 128 and 129 with a bottom perforated plate comprising a baffle structure inlet 104 and a top perforated plate comprising a baffle structure outlet 106. The sealed duct structure 102 and sealed baffle structure 108 are sealed to each other, and the sealed duct structure 102 is sealed to the susceptor floor 463 at joint 118 so that gas cannot avoid flowing through the sealed baffle structure 108. The sealed duct structure 102 comprises at least two pieces 119, 120, and 121, upper ring 122 and lower ring 123 which together form several sealed joints 124, 125, 166, 168, 170, 172, and 174. The support bars 119, 120, and 121, and lower ring 123 support the weight of the sealed baffle structure 108. A cover plate 110 preferably adjoins the sealed duct structure 102 disposed over the baffle structure outlet 106. The cover plate 110 serves to support the porous structure fixtures. Cover plate 110 is adapted for use with a pressure gradient CVI/CVD process and comprises a plurality of apertures 114 and 116 with each aperture providing reactant gas to an annular porous wall. The cover plate 110 is sealed to the sealed duct structure 102 by a compliant gasket placed in the joint between the sealed duct structure 102 and the cover plate 110. The perforated plates 128 and 129 are coterminous and arranged in a stack that defines a baffle structure perimeter 132. Each sealed baffle structure plate 128 comprises an array of perforations 130, with the array of perforations 130 of one susceptor plate 128 being misaligned with the array of perforations 131 of an adjacent susceptor plate 129. This arrangement greatly facilitates transfer of heat by radiation from the susceptor wall 464 directly to the perforated plates 128 and 129. The heat is transferred by conduction along plates 128 and 129 and to the gas by forced convection. The baffle structure perimeter 132 is sealed by compliant gaskets 134 and comprises the outer plane-wise limit of each susceptor plate 128 and 129 and is disposed in close proximity to the susceptor wall 464. The compliant gaskets 134 also serve to space the perforated plates 128 and 129 from each other. The sealed duct structure 102 preferably defines a ledge 136 upon which said sealed baffle structure 108 rests. In the embodiment presented, the support bars 119, 120, and 121 define the ledge in combination with lower ring 123. A plurality of posts 140 may be provided that facilitate loading the baffle structure 108 into the furnace and also further support the sealed baffle structure 108 and cover plate 110. Each post 140 comprises an enlarged portion that defines a seat (not shown) which rests on the susceptor floor 463. The sealed baffle structure 108 rests upon the seat. The various components of preheater 100 are preferably formed from monolithic graphite. The various sealed joints are preferably formed using compliant gaskets and/or graphite cement. Suitable compliant gaskets may be formed from a flexible graphite such as EGC Thermafoil[®] and Therma-braid[®] brand flexible graphite sheet and ribbon-pack available from EGC Enterprises Incorporated, Mentor, Ohio, U.S.A. Comparable materials are available from UCAR Carbon Company Inc., Cleveland, Ohio, U.S.A.

The porous walls 452 and 472 of Figure 15 may be formed from stacks of annular porous structures, which is particularly preferred for manufacturing aircraft brake disks. Referring now to Figure 17, a preferred fixture 200 is presented for densifying a stack of annular porous structures 22 by a pressure gradient CVI/CVD process. The fixture 200 is described in more detail in a copending United States patent application entitled APPARATUS FOR USE WITH CVI/CVD PROCESSES, filed the same day as the present application naming James W. Rudolph, Mark J. Purdy, and Lowell D. Bok as inventors. Fixture 200 is preferably used with the preheater 100 of Figure 16. The porous structures 22 are arranged in a stack 202. The fixture comprises a base plate 204, a spacing structure 206, and a top plate 208. The top plate 208 optionally has an aperture 210 which is sealed by a cover plate 212, compliant gasket 213, and weight 214. The base plate 204 is adapted to engage the cover plate 110 and has a base plate aperture (item 216 in Figure 18) that aligns with one of the cover plate apertures 114 or 116. The base plate 204 is preferably located by a plurality of conical pins 226. The base plate 204 has mating conical base plate holes that are aligned with and receive the conical pins 226. This arrangement facilitates aligning the base plate aperture with a corresponding cover plate aperture. The base plate 204 is preferably sealed to the cover plate 110 by use of a compliant gasket.

The top plate 208 is spaced from and faces the base plate 204. The spacing structure 206 is disposed between and engages the base plate 204 and the top plate 208. In the embodiment presented, the spacing structure comprises a plurality of spacing posts 218 disposed about the stack of porous structures and extending between the base plate 204 and the top plate 208. Each post 218 has pins 220 at either end that are received in mating holes 224 in base plate 204 and top plate 208. The spacing structure 206 preferably comprises at least three posts 218. The spacing structure 206 could also be formed as a single piece, and other arrangements for engaging the base plate 204 and top plate 208 are possible, any of which are considered to be within the purview of the invention. At least one ring-like spacer 234 is disposed within the stack 202 of porous structures 22 between each pair of neighboring porous structures 22. The ring-like spacer 234 encircles the neighboring porous structure apertures 23. At least one of the ring-like spacers 234 is preferably disposed between the base plate 204 and porous structure 22 adjacent the base plate 204, and between the top plate 208 and porous structure 22 adjacent the top plate 208. The base plate 204, the stack of porous structures 202, and the at least one ring-like spacer 234 define an enclosed cavity 236 extending from the base plate aperture (item 216 in Figure 18), including each porous structure aperture 23, and terminating proximate the top plate 208. According to a certain embodiment, the outside diameter of ring-like spacer 234 is about 21.9 inches) and the spacer inside diameter is about 19.9 inches) for processing annular porous structures 22 having an outside diameter of about 21 inches. The ring-like spacers are preferably at least 0.25 inch thick.

Referring to Figure 18, a preferred fixture 201 is presented for pressure gradient CVI/CVD densifying simultaneously a large number of porous structures 22. The spacing structure 207 comprises at least one intermediate plate 272 disposed between the base plate 204 and the top plate 208 that divides the stack of porous structures 203. The posts 218 extend between the top plate 208 and one of the intermediate plates 272, between the base plate 204 and another of the intermediate plates 272, and between adjacent pairs of intermediate plates 272. In other respects, fixture 201 is essentially identical to fixture 200. Each intermediate plate 272 has an intermediate plate aperture 274 therethrough is sandwiched between a pair of the porous structures 22. The enclosed cavity 286 further includes each intermediate plate aperture 274. At least one of the ring-like spacers 234 is disposed on either side of and sealed to the intermediate plate 272 between the intermediate plate 272 and the porous structures 22. Multiple fixtures 201 may be stacked. In such case, the base plate 204 from one fixture 201 engages the top plate 208 of a lower fixture 201 with the upper fixture base plate aperture 216 in fluid communication with the lower fixture top plate aperture 210. Thus, the enclosed cavity extends from one fixture 201 to the next until being terminated by the cover plate 212 disposed over the uppermost top plate aperture 210. As shown more clearly in this view, the base plate 204 is provided with conical holes 230 that receive a conical portion of the conical pins 226, and the cover plate 110 is provided with holes 228 that receive a cylindrical portion of the conical pins 226.

Referring now to Figure 28, an alternative fixture 300 for pressure gradient densifying a stack of porous structures 302 is presented. Fixture 299 is essentially identical to fixture 200, except stack 302 comprises "OD" (outside diameter) ring-like spacers 234 disposed around the outside diameter of each porous structure 22 alternated with "ID" (inside diameter) ring-like spacers 284 disposed around the inside diameter of each porous structure. The OD ring-like spacers 234 preferably have an inside diameter 233 slightly less than the porous structure outside diameter 608, and an outside diameter 235 that is generally coterminous with the porous structure outside diameter 608. The ID ring-like spacers 284 preferably have an outside diameter 286 slightly greater than the porous structure inside diameter 610, and an inside diameter 288 that is generally coterminous with the porous structure inside diameter 610. With ID ring-like spacers 284, the porous structure outside diameter 608 is greater than the outside diameter 286 of the ring like spacer 284. The wall thickness of each ring-like spacer 234 and 284 is preferably minimized in order to maximize exposure of the porous structure surface area to the reactant gas as it enters or leaves each porous structure 22. Referring to Figure 29, an alternative fixture 301 for pressure gradient densifying a stack of porous structures 303 is presented. Fixture 301 is essentially identical to fixture 200, except stack 303 comprises all "ID" ring-like spacers 284 disposed around the inside diameter of each porous structure.

The various components of fixtures 200, 201, 299 and 301 are preferably formed from graphite. The various joints comprised within the fixtures are preferably sealed using compressible ring-like gaskets from a flexible graphite material, as previously disclosed. If the porous structures 22 are compressible, they may be compressed directly against the ring-like spacers 234 to provide a sufficient seal and eliminate the need for compressible gaskets between the porous structures 22 and ring-like spacers 234. The ring-like spacers prior to use are preferably seal-coated with a surface deposition of pyrolytic carbon which facilitates removal of the ring-like spacer from a densified porous structure following deposition of the matrix.

Fixtures similar to fixtures 200 and 201 may be used in a conventional CVI/CVD process in which the ring-like spacers 234 are replaced by spacer blocks that separate the porous structures and permit the reactant gas to freely pass through, over, and around the porous structures 22. In such case, cover plate 110 may be replaced by cover plate 152 of Figure 22 in order to promote dispersion of the reactant gas throughout the furnace volume. Cover plate 152 comprises an array of perforations 153. Sealing the various joints comprised within a fixture adapted for a conventional CVI/CVD process is not necessary or desirable.

Referring now to Figure 19, a CVI/CVD process is presented according to an aspect of the invention. According to a preferred embodiment, a multitude of annular porous carbon structures are disposed within a CVI/CVD furnace such as furnace 400 (Figure 15) using multiple fixtures such as fixture 201 (Figure 18) which are sealed to multiple preheaters such as preheater 100. Reactant gas is supplied to the furnace using an apparatus such as the gas supply apparatus 402 (Figure 15). The furnace is heated until conditions are stabilized, and a first carbon matrix is deposited within the porous structures by a pressure gradient CVI/CVD process. More support for the porous structures than depicted in Figures 17 and 18 during the pressure gradient CVI/CVD process is not necessary since the porous structures do not sag during the pressure gradient CVI/CVD process. The porous structures are then subjected to a heat treatment process without removing the porous structures from the furnace or from the fixtures. Alternatively, the porous structures may be removed from the furnace and pressure gradient CVI/CVD fixtures before the heat treatment process. The heat treatment process is conducted at a higher temperature than the previous deposition process temperatures which increases graphitization of the first carbon matrix. Following heat treatment, the porous structures are then removed from the furnace and surface machined in order to derive an accurate bulk density measurement. Machining the surface may also increase open porosity at the surface. A second carbon matrix is then deposited within the porous structures by a conventional CVI/CVD process. Thus, the second matrix overlies the first matrix. After reaching final density, the densified structures are machined into final parts. In certain embodiment, the pressure gradient CVI/CVD process and

conventional CVI/CVD process are conducted at about 1750-1900 °F, and heat treatment is conducted at about 3300-4000 °F. Thus, the first matrix has a greater degree of graphitization than the second matrix due to the intermediate heat treatment process.

Referring now to Figure 20, an alternative process is presented that begins with a pressure gradient CVI/CVD process in which a first carbon matrix is deposited within the porous structures. The porous structures are then subjected to a heat treatment process without removing the porous structures from the furnace or from the fixtures. A second carbon matrix is then deposited in another pressure gradient CVI/CVD process that immediately follows the heat treatment process without removing the porous structures from the furnace or the fixtures. Alternatively, the porous structures may be removed from the furnace and pressure gradient CVI/CVD fixtures before the heat treatment process, and replaced in the pressure gradient CVI/CVD fixtures before the second pressure gradient CVI/CVD process. The porous structures are then subjected to a surface machining operation. Further second carbon matrix is then deposited in a conventional CVI/CVD process and the porous structures are machined into final parts. Leaving the porous structures in the same furnace and fixtures during the first and second pressure gradient processes and the heat treatment process results in a "continuous" process. Additional support blocks between adjacent pairs of porous structures in the pressure gradient CVI/CVD fixtures may be necessary in order to prevent sagging during the heat treatment process.

Referring now to Figure 21, an alternative process is presented that begins with a pressure gradient CVI/CVD process in which a first carbon matrix is deposited within the porous structures. The porous structures are surface machined and a second carbon matrix is then deposited in a conventional CVI/CVD process followed by a heat treatment process. After heat treatment, the fully densified porous structures are then machined into final parts. It is evident that the sequences of the Figure 19-21 processes may be rearranged, and additional steps inserted, without departing from the invention.

The first carbon matrix and second carbon matrix preferably comprise a substantially rough laminar microstructure. A rough laminar microstructure has a greater density (about 2.1 g/cc), greater thermal conductivity, and lesser hardness than smooth laminar microstructure (1.9-2.0 g/cc or less). Rough laminar microstructure is particularly preferred in certain carbon/carbon aircraft brake disks. Microstructure may be optically characterized as described by M.L. Lieberman and H.O. Pierson, Effect of Gas Phase Conditions on Resultant Matrix Pyrocarbons in Carbon/Carbon Composites, 12 Carbon 233-41 (1974).

Referring now to Figure 23, a densified porous structure 600 manufactured according to either the Figure 19, 20 or 21 process is presented. The densified porous structure 600 comprises a first circumferential zone 512 adjacent the inside circumferential surface 82, and a second circumferential zone 514 adjacent the outside circumferential surface 84. The first and second circumferential zones 512 and 514 extend all the way through the thickness of the densified porous structure 600 and are bounded by the opposing surfaces 78 and 80. Densified porous structure 510 comprises a first carbon matrix deposited within a porous structure comprised of carbon fibers according to a pressure gradient CVI/CVD process. According to a preferred embodiment, the first carbon matrix is deposited by a process using fixtures 200 and/or 201 having all "OD" ring-like spacers 234 (Figures 17 and 18) which is similar to the process described in relation to Figure 5, resulting in the first carbon matrix being deposited unevenly in a density distribution similar to densified porous structure 330 of Figure 11. The first circumferential zone 512 is subjected to a greater reactant gas pressure than the second circumferential zone 514 during the pressure gradient CVI/CVD densification process which causes the first circumferential zone 512 to experience a greater bulk density gain than the second circumferential zone 514. According to a certain embodiment, the second circumferential zone 514 has about 15% less of the first carbon matrix per unit volume relative to the first circumferential zone 512, and the first carbon matrix preferably has a substantially rough laminar microstructure. The second circumferential zone 514 generally has at least 10% less of the first carbon matrix per unit volume relative to the first circumferential zone 512, and may have 20%, 30%, 40% or less of the first carbon matrix. Densified porous structure 510 also comprises a second carbon matrix overlying the first carbon matrix that is deposited by a conventional CVI/CVD process resulting in the densified porous structure 600 having a final density distribution similar to densified porous structure 340 of Figure 12. The second carbon matrix also preferably has a substantially rough laminar microstructure. The first and second carbon matrices preferably have at least 90% rough laminar microstructure, more preferably at least 95% rough laminar microstructure, and in certain preferred embodiments 100% rough laminar microstructure.

The first carbon matrix may be heat treated which causes the first carbon matrix to be more graphitized than the second carbon matrix. Increasing graphitization increases the apparent density and thermal conductivity. Thus, the original density gradient from the pressure gradient CVI/CVD process may be identified in the densified porous structure 600 after deposition of the second carbon matrix. If the first carbon matrix has a distribution as shown in Figure 11, the first circumferential portion 512 has a generally greater thermal conductivity than the second circumferential portion 514, and a generally greater apparent density than the second circumferential portion 514 even after the second carbon matrix is deposited. Closed porosity remaining within the densified porous structure 600 affects the measurement of apparent density. Porosity effects may be minimized by measuring apparent density of crushed samples which will be referred to herein as crushed apparent density. According to a certain technique, crushed apparent density is measured

by cutting a specimen from a densified porous structure and fracturing the specimen between parallel steel platens of a load testing machine. The specimen is preferably fractured in a manner that maintains the specimen in one piece. This may be accomplished by compressing the sample past the yield point without fragmentation. Apparent density is then measured according to the Archimedes technique using mineral spirits such as Isopar M (synthetic isoparaffinic hydrocarbon) available from Exxon Chemical Americas, Houston, Texas, U.S.A. Vacuum is used to force the mineral spirits into the structure. Apparent density is a measurement of the density of the material that is impervious to penetration by the mineral spirits. Fracturing the specimen opens previously closed porosity that was impervious to penetration by the mineral spirits and minimizes porosity effects. Alternatively, crushed apparent density of a pulverized sample may be measured using a helium pycnometer. Measurements of densified porous structures processed similar to densified porous structure 600 demonstrated that the crushed impervious density adjacent the inside circumferential surface 82 was consistently at least 0.2% greater, and may be as much as 0.4% and 0.5% greater, than adjacent the outside circumferential surface 84. Thus, crushed apparent density tends to generally decrease from the inside surface 82 to the outside surface 84.

Thermal conductivity of densified porous structures similar to densified porous structure 600 (as described in the immediately preceding paragraph) was measured in two directions: normal to the opposing surfaces 78 and 80 which will be referred to as "thermal flat conductivity", and normal to the circumferential surfaces 82 and 84 (in the radial direction) which will be referred to as "thermal edge conductivity." Thermal flat conductivity of circumferential portion 514 was at least 5% less than circumferential portion 512 when measured at the opposing surfaces 78 and 80. Thermal flat conductivity of circumferential portion 514 was at least 12% less than circumferential portion 512 at one-half of the distance between opposing surfaces 78 and 80. Thermal edge conductivity of circumferential portion 514 was at least 5% less than circumferential portion 512 when measured at the opposing surfaces 78 and 80. Thermal edge conductivity of circumferential portion 514 was at least 4% less than circumferential portion 512 when measured at one-half of the distance between opposing surfaces 78 and 80. Thus, thermal conductivity tends to generally decrease from the inside circumferential portion 512 to the outside circumferential portion 514. This trend is induced by the first matrix being more graphitized than the second matrix.

The following examples further illustrate various aspects of the invention.

EXAMPLE 1

A base-line was established for a conventional CVI/CVD process as follows. A fibrous textile structure about 1.5 inch thick was manufactured according to Figures 1 through 4 of United States Patents 4,790,052 starting with a 320K tow of unidirectional polyacrylonitrile fiber. An annular porous structure was then cut from the textile structure having an outside diameter of about 7.5 inch, an inside diameter of about 2.5 inch. The annular porous structure was then pyrolyzed to transform the fibers to carbon. The pyrolyzed porous structure, having a bulk density of 0.49 g/cc, was then placed in a furnace similar to furnace 11 of Figure 14. Pressure was reduced to 10 torr inside the furnace volume and the furnace was heated and stabilized at a temperature of about 1860°F when measured by a temperature sensor positioned as temperature sensor 78 of Figure 14. A reactant gas mixture was introduced as described in relation to Figure 14 and allowed to freely disperse over and around the porous structure in a manner typical of a conventional CVI/CVD process. The reactant gas mixture was comprised of 87% (volume percent) natural gas and 13% propane at a flow rate of 4000 sccm (standard cubic centimeters per minute) and a residence time of about 1 second in the reactor volume. The natural gas had a composition of 98.4% methane (volume percent), 1.80% ethane, 0.50% propane, 0.15% butane, 0.05% pentane, 0.70% carbon dioxide, and 0.40% nitrogen. The process was stopped three times to measure bulk density gain of the porous structure. Total deposition process time was 306 hours. An average rate of deposition was calculated for each of the three densification runs. The test conditions and data from this example are presented in Table 1, including cumulative deposition time (Cum. Time) and total density gain (Density Gain) at each cumulative time noted. The carbon matrix deposited within the densified porous structure at the end of the process comprised nearly all rough laminar microstructure with minimal deposits of smooth laminar microstructure at the surface of the porous structure.

TABLE 1

Cum. Time (hour)	Gas Flow Rate (sccm)	Part Temp. (F°)	Density Gain (g/cc)
41	4000	1857	0.310
166	4000	1860	0.886
306	4000	1855	1.101

EXAMPLE 2

An annular porous structure having a thickness of 1.6 inch, an outside diameter of 6.2 inch, and an inside diameter of 1.4 inch was cut from a fibrous textile structure and processed according to Example 1 by a conventional CVI/CVD process. The test conditions and data from this example are presented in Table 2.

TABLE 2

Cum. Time (hour)	Gas Flow Rate (sccm)	Part Temp. (F°)	Density Gain (g/cc)
92	4000	1858	0.370

EXAMPLE 3

Two annular porous structures (Disks A and B), prepared from a fibrous textile structure and having the same dimensions as described in Example 1, were densified by a pressure gradient CVI/CVD process using a furnace similar to furnace 10 of Figure 1, a fixture similar to fixture 2 of Figure 2 having ID/OD spacers, and the reactant gas mixture of Example 1. The test conditions and data from this example are presented in Table 3. Furnace pressure was 10 torr. Temperature of the gas stream was estimated to be 1740 °F when measured by a temperature sensor such as temperature sensor 74 of Figure 1. The gas was forced to flow through the porous structure, as previously described in relation to Figure 2, at a flow rate of 4000 sccm. The carbon matrix deposited within Disk A comprised all rough laminar microstructure. The microstructure of Disk B was not evaluated. Disk A was cut into smaller samples and the bulk density measurements of these samples were determined using the Archimedes method, and demonstrated a density profile similar to Figure 8.

TABLE 3

Disk	Run Time (Hour)	Gas Flow Rate (sccm)	Part Temp. (F°)	Density Gain (g/cc)
A	165	4000	1861	1.106
B	123	4000	1859	0.928

EXAMPLE 4

Three annular porous structures (Disks A, B and C) were prepared and individually densified by a pressure gradient CVI/CVD process according to Example 3 except that the porous structures were flipped part way through the process in order to obtain a more uniform final density distribution. Temperature of the gas stream was approximately 1740 °F when measured by a temperature sensor such as temperature sensor 74 of Figure 1. The test conditions and data from this example are presented in Table 4. The carbon matrix deposited within Disks A and C was all rough laminar before the flip, and essentially smooth laminar after the flip. The microstructure of Disk B was not determined. The final densified porous structures had density profiles similar to Figure 9.

TABLE 4

Disk	Cum. Time (hour)	Gas Flow Rate (sccm)	Part Temp. (F°)	Density Gain (g/cc)
A	72 Flip	4000	1859	0.743
	96	4000	1859	0.853
	111	4000	1855	1.034
B	49 Flip	4000	1854	0.619
	74	4000	1849	0.898
C	49 Flip	4000	1858	0.825
	75	4000	1853	0.915

EXAMPLE 5

Two annular porous structures, prepared from a fibrous textile structure and having the same dimensions as described in Example 1, were simultaneously densified by a pressure gradient CVI/CVD process with a fixture similar to fixture 6 of Figure 4 having all "ID" spacers, and the reactant gas mixture of Example 1. Temperature of the gas stream was estimated 1745 °F when measured by a temperature sensor such as temperature sensor 74 of Figure 1. The test conditions and data from this example are presented in Table 5. Density gain on Table 5 is an average for the two disks. The carbon matrix deposited within the densified porous structure at the end of the process comprised all rough laminar microstructure. Computed tomography scans of the disk demonstrated density profiles similar to Figure 10.

TABLE 5

Cum. Time (hour)	Gas Flow Rate (sccm)	Part Temp. (F°)	Density Gain (g/cc)
24.4	8000	1860	0.262
70.7	8000	1856	0.593

EXAMPLE 6

Four annular porous structures, prepared from a fibrous textile structure and having the same dimensions as described in Example 1, were densified by a pressure gradient CVI/CVD process using a fixture similar to fixture 8 of Figure 5 having all "OD" spacers, and the reactant gas mixture of Example 1. Two disks were simultaneously densified (Disk Pair A and B) and reactant gas flow rate was doubled to maintain a flow rate of 4000 sccm per disk. Temperature of the gas stream was approximately 1750 °F when measured by a temperature sensor such as temperature sensor 74 of Figure 1. The test conditions and data from this example are presented in Table 6. The density gain on Table 6 is an average for each disk pair. The carbon matrix deposited within the densified porous structure at the end of the process comprised all rough laminar microstructure. Computed tomography scans of Disk Pair B demonstrated density profiles similar to Figure 11.

TABLE 6

Disk Pair	Run Time (hour)	Gas Flow Rate (sccm)	Part Temp. (F°)	Density Gain (g/cc)
A	70	8000	1860	0.951
B	70	8000	1855	0.861

EXAMPLE 7

An annular porous structure was prepared from a fibrous textile structure, having the same dimensions as described in Example 2, and densified by a pressure gradient CVI/CVD process using a fixture similar to fixture 7 of Figure 7 having all "ID" seals with a reverse flow process, and the reactant gas mixture of Example 1. Temperature of the gas stream was estimated (1730 °F) when measured by a temperature sensor such as temperature sensor 74 of Figure 1. The reactant gas was forced to flow through the porous structure as previously described in relation to Figure 7 at a flow rate of 3000 sccm (the flow was lowered since the disk was smaller than the disks used in Examples 3-6). The test conditions and data from this example are presented in Table 7. The carbon matrix deposited within the densified porous structure at the end of the process comprised mostly smooth laminar microstructure.

TABLE 7

Cum. Time (hour)	Gas Flow Rate (sccm)	Part Temp. (F°)	Density Gain (g/cc)
50	3000	1854	0.987

Referring now to Figure 24, the data presented on Tables 1 through 7 is depicted in graphical form. The data from Tables 1 and 2 is presented as a single smoothed curve 516 representing conventional CVI/CVD. The data from Tables

3 and 4 is presented as a single smoothed curve 518 representing pressure gradient CVI/CVD using "ID/OD" spacers. The data from Table 5 is presented as a single smoothed curve 520 representing pressure gradient CVI/CVD using all "ID" spacers. The data from Table 6 is presented as a single smoothed curve 522 representing pressure gradient CVI/CVD using all "OD" spacers. The data from Table 7 is presented as curve 524 representing reverse flow pressure gradient CVI/CVD with all "ID" spacers. Densification rates increased by factors from about one and one-half to five times conventional CVI/CVD densification rates. Time to achieve a bulk density increase of 1 g/cc was reduced by about 25% to 80% relative to conventional CVI/CVD time. The importance of eliminating as many leaks as possible is apparent from Figure 24. Any leakage tends to decrease the densification rate from the maximum attainable rate. Increased densification rates may be achieved even with a small amount of leakage. Thus, some leakage may occur while remaining within the purview of the invention.

Referring now to Figure 25, curves representing densification rate versus normalized flow are presented. The normalized flow is indicated as F^* and represents a quantity of flow per unit of disk volume (for example, 4000 sccm per 1000 cc disk volume = 4 min^{-1}). Additional tests were run according to Example 6 and 7 above except flow rates of reactant gas were varied from one test to the next. The data from tests conducted according to Example 6 with varying flow are presented on Tables 8, and the data from tests conducted according to Example 7 with varying flow are presented on Table 9. A curve 526 represents conventional CVI/CVD. Data from Table 8 is presented as curve 528 which represents pressure gradient CVI/CVD with all "OD" spacers (Figure 5). Data from Table 9 is presented as curve 530 which represents reverse flow pressure gradient CVI/CVD with all "ID" spacers (Figure 7).

TABLE 8

Cum. Time (hour)	Gas Flow Rate (sccm)	Part Temp. (°F)	Density Gain (g/cc)	Average Deposition Rate (g/cc/h)
50	1000	1853	0.232	0.0046
50	2000	1856	0.414	0.0083
50	4000	1851	0.547	0.0109
70	8000	1858	0.906	0.0129

TABLE 9

Cum. Time (hour)	Gas Flow Rate (sccm)	Part Temp. (°F)	Density Gain (g/cc)	Average Deposition Rate (g/cc/h)
50	500	1852	0.328	0.0065
50	1000	1853	0.498	0.0100
56	2000	1855	0.920	0.0164
46	3000	1854	0.987	0.0215
38	4000	1852	0.919	0.0242

Referring now to Figure 26, curves representing densification rate versus normalized flow are presented. Additional tests were run according to Example 6 (pressure gradient with all "OD" spacers) above except the furnace volume pressure and flow rates of reactant gas were varied from one test to the next. The data from these tests is presented in Table 10. Data from Table 10 is presented as three curves 532, 534, and 536. Curve 532 represents data at a furnace volume pressure of 10 torr when measured by a pressure sensor such as sensor 72 of Figure 1. Curve 534 represents data at a furnace volume pressure of 25 torr when measured by a pressure sensor such as sensor 72 of Figure 1. Curve 536 represents data at a furnace volume pressure of 50 torr when measured by a pressure sensor such as sensor 72 of Figure 1. The matrix deposited in all of these tests comprised all rough laminar microstructure. As demonstrated by Figure 26, additional gains in densification rate may be realized by increasing the furnace volume pressure (Reactor Pressure) while maintaining a desired rough laminar microstructure. This was a surprising discovery.

TABLE 10

Cum. Time (hour)	Reactor Pressure (torr)	Gas Flow Rate (sccm)	Part Temp. (°F)	Density Gain (g/cc)	Average Deposition Rate (g/cc/h)
50	10	2000	1856	0.414	0.0083
50	10	4000	1851	0.547	0.0109
70	10	8000	1858	0.906	0.0129
50	25	2000	1853	0.449	0.0090
50	25	4000	1853	0.611	0.0122
50	50	2000	1853	0.493	0.0099
50	50	4000	1852	0.683	0.0137

Referring now to Figure 27, pressure differential across the porous structure versus bulk density is presented for several reactant gas flow rates. Additional tests were run according to Example 6 with varying flow rates. Data from these tests is presented in Table 11. The data from Table 11 is presented in Figure 27 as a first set of curves 538 for a flow rate of 1000 sccm per disk, a second set of curves 540 for a flow rate of 2000 sccm per disk, and a third set of curves 542 for a flow rate of 4000 sccm per disk. The matrix deposited in all of these tests comprised all rough laminar microstructure. Table 11 includes the initial pressure differential across the porous structures (Init. Delta P), final pressure differential across the porous structures (Final Delta P), and furnace volume pressure (Reactor Pressure) which was maintained constant. As demonstrated by Figure 27, the pressure gradient across the porous structure may be at least as high as 80 torr (which indicates 90 torr on the high pressure side of the porous structure) while maintaining a desired rough laminar microstructure.

TABLE 11

Cum. Time (h.)	Gas Flow Rate (sccm)	Temp (°F)	Density Gain (g/cc)	Average Deposit. Rate (g/cc/h)	Init. Delta P (torr)	Final Reactor Delta Pressure P (torr)
50	2000	1856	0.414	0.0083	5	1210
50	2000	1853	0.449	0.0090	10	025

50	4000	1851	0.547	0.0109	14	3210
50	4000	1853	0.611	0.0122	15	3925
50	4000	1852	0.683	0.0137	15	4250
70	8000	1860	0.951	0.0136	38	8110
70	8000	1855	0.861	0.0123	32	5610

Tests have demonstrated that the pressure gradient CVI/CVD process according to the invention may be conducted with a part temperature in the range of 1800-2000 °F, a reactor pressure in the range of 10-150 torr, normalized reactant gas flow rate (F^*) in the range of 0.4-10 min^{-1} , and with a hydrocarbon reactant gas mixture of natural gas and 0-40% (volume percent) propane. Conducting the process within these ranges generally produces a rough laminar and/or smooth laminar microstructure. Conducting the process with all of these process parameters at or near the high extreme of each of these ranges may result in tarring or sooting. Other carbon bearing gases, pressures, and temperatures known in the art for CVI/CVD processes may be substituted without departing from the invention.

Densifying a porous structure by a pressure gradient CVI/CVD process according to the invention followed by a conventional CVI/CVD process produces a densified porous structure having a more uniform density distribution than a comparable porous structure densified only by a conventional CVI/CVD process. According to a certain embodiment, for example, an annular porous carbon structure having an inside diameter of about 10.5 inches (indicated as 602 in

Figure 23), a web (indicated as 604 in Figure 23) of about 5.25 inches, and a thickness (indicated as 606 in Figure 23) of about 1.25 inches, is densified first with a carbon matrix deposited by a pressure gradient CVI/CVD process (Example 6 conditions) using a fixture such as fixture 201 (Figure 18) in furnace such as furnace 400 (Figure 15) resulting in a density distribution similar to densified structure 330 of Figure 11. Carbon matrix is further deposited by a conventional CVI/CVD process (Example 1 conditions) resulting in a density distribution similar to densified structure 340 of Figure 12, and having a mean bulk density of about 1.77 g/cc. According to standard statistical practice, the standard deviation of the bulk density throughout the densified structure is about 0.06 g/cc. The standard deviation of the bulk density throughout a comparable porous carbon structure densified to an equivalent mean bulk density by only conventional CVI/CVD processes is about 0.09 g/cc. Thus, a porous structure densified by a pressure gradient CVI/CVD process followed by a conventional CVI/CVD process is more uniform than a porous structure densified by only conventional CVI/CVD processes. Circumferential as well as total variation is reduced. Uniformity is desirable for carbon/carbon aircraft brake disks.

The standard deviation of the bulk density throughout a carbon/carbon structure manufactured according to the invention is preferably less than or equal to 0.07 g/cc, is more preferably less than or equal to 0.06 g/cc or 0.05 g/cc, and is most preferably less than or equal to 0.04 or 0.03 g/cc. Coefficient of variation of bulk density in any densified porous structure is preferably less than or equal to 4%, more preferably less than or equal to 3.5% or 3%, and most preferably less than or equal to 2.3% or 1.8%.

It is evident that many variations are possible without departing from the scope of the invention as defined by the claims that follow.

A CVI/CVD process, comprising the steps of:

partially densifying a porous structure within a CVI/CVD furnace by depositing a first matrix within said porous structure with a pressure gradient CVI/CVD process in which a first portion of said porous structure is subjected to a greater pressure than a second portion of said porous structure and said first portion has a greater bulk density gain than said second portion; and, subsequently densifying said porous structure by depositing a second matrix within said porous structure with at least one additional densification process in which said second portion has a greater bulk density gain than said first portion.

The process as above wherein said additional densification process is a conventional CVI/CVD process.

The process as above wherein said additional densification process is a pressure gradient CVI/CVD process in which said second portion is subjected to a higher pressure than said first portion.

The process as above wherein said additional densification process is a resin impregnation process, and further comprising the step of charring said resin.

The process as above further comprising the step of heat treating said partially densified porous structure at a temperature greater than said pressure gradient CVI/CVD process before said step of subsequently densifying the porous structure by at least one additional densification process.

The process as above wherein said porous structure is a carbon porous structure and said pressure gradient CVI/CVD process deposits a carbon matrix within said porous structure.

The process as above wherein said porous structure is annular and has two generally planar opposing surfaces, and said first portion includes one of said two opposing surfaces, and said second portion includes the other of said two opposing surfaces.

The process as above wherein said porous structure is annular and has an inside circumferential surface and an outside circumferential surface, and said first portion includes said inside circumferential surface, and said second portion includes said outside circumferential surface.

The process as above wherein said porous structure is annular and has an inside circumferential surface and an outside circumferential surface, and said first portion includes said outside circumferential surface, and said second portion includes said inside circumferential surface.

The process as above wherein said porous structure is annular and has an inside circumferential surface and an outside circumferential surface, and said first portion includes said inside circumferential surface, and said second portion includes said outside circumferential surface.

The process as above wherein said porous structure is annular and has two generally parallel planar surfaces bounded by an inside circumferential surface and an outside circumferential surface spaced from and encircling said inside circumferential surface, and said first portion includes said inside circumferential surface and one of said two generally parallel planar surfaces, and said second portion includes said outside circumferential surface and the other of said two generally parallel planar surfaces.

The process as above wherein said porous structure is annular and has two generally parallel planar surfaces bounded by an inside circumferential surface and an outside circumferential surface spaced from and encircling said

inside circumferential surface, and said first portion includes said outside circumferential surface and one of said two generally parallel planar surfaces, and said second portion includes said inside circumferential surface and the other of said two generally parallel planar surfaces.

5 The process as above further comprising the step of heat treating said porous structure at a temperature greater than said pressure gradient CVI/CVD process after said pressure gradient CVI/CVD process and before said step of subsequently densifying said porous structure.

The process as above wherein said step of heat treating said porous structure follows said pressure gradient CVI/CVD process without removing said porous structure from said CVI/CVD furnace.

A CVI/CVD process, comprising the steps of:

10

partially densifying a multitude of annular fibrous carbon structures within a CVI/CVD furnace by depositing a first carbon matrix within said annular fibrous carbon structure with a pressure gradient CVI/CVD process in which a first portion of each annular fibrous carbon structure is subjected to a higher pressure than a second portion of each annular fibrous carbon structure and said first portion has a greater bulk density gain than said second portion; and,

15

subsequently densifying said multitude of annular fibrous carbon structures by depositing a second carbonaceous matrix within each annular fibrous carbon structure with at least one additional densification process in which said second portion has a greater bulk density gain than said first portion.

20

The process as above wherein each annular fibrous carbon structure has two generally parallel planar surfaces, and said first portion includes one of said two generally parallel planar surfaces, and said second portion includes the other of said two generally parallel planar surfaces.

25

The process as above wherein each annular fibrous carbon structure has an inside circumferential surface and an outside circumferential surface, said first portion includes said inside circumferential surface, and said second portion includes said outside circumferential surface.

The process as above wherein each annular fibrous carbon structure has an inside circumferential surface and an outside circumferential surface, and said first portion includes said outside circumferential surface, and said second portion includes said inside circumferential surface.

30

The process as above wherein each annular fibrous carbon structure has an inside circumferential surface and an outside circumferential surface, and said first portion includes said inside circumferential surface, and said second portion includes said outside circumferential surface.

35

The process as above wherein each annular fibrous carbon structure has two generally parallel planar surfaces bounded by an inside circumferential surface and an outside circumferential surface spaced from and encircling said inside circumferential surface, and said first portion includes said inside circumferential surface and one of said two generally parallel planar surfaces, and said second portion includes said outside circumferential surface and the other of said two generally parallel planar surfaces.

40

The process as above wherein each annular fibrous carbon structure has two generally parallel planar surfaces bounded by an inside circumferential surface and an outside circumferential surface spaced from and encircling said inside circumferential surface, and said first portion includes said outside circumferential surface and one of said two generally parallel planar surfaces, and said second portion includes said inside circumferential surface and the other of said two generally parallel planar surfaces.

The process as above further comprising the step of heat treating said annular fibrous carbon structure at a temperature greater than said pressure gradient CVI/CVD process after said pressure gradient CVI/CVD process and before said step of subsequently densifying said annular fibrous carbon structure.

45

The process as above wherein said step of heat treating said porous structure follows said pressure gradient CVI/CVD process without removing said porous structure from said CVI/CVD furnace.

A CVI/CVD process, comprising the steps of:

50

heating a porous carbon structure to a temperature of at least 1750 °F;

heating a hydrocarbon reactant gas to a temperature of at least 1650 °F;

partially densifying said porous carbon structure by forcing said reactant gas to pass through said porous carbon structure from a first portion of said fibrous structure to a second portion of said porous carbon structure, said first portion having a greater bulk density gain than said second portion; and,

55

subsequently densifying said porous carbon structure by depositing a second matrix within said porous carbon structure with at least one additional densification process in which said second portion has a greater bulk density gain than said first portion.

The process as above wherein said second matrix is a carbon matrix and said additional densification process is a

conventional CVI/CVD process.

The process as above wherein said additional densification process comprises the steps of:

heating a porous carbon structure to a temperature of at least 1750 °F;
 heating a hydrocarbon reactant gas to a temperature of at least 1650 °F; and,
 passing said reactant gas around said porous structure.

The process as above further comprising the step of heat treating said porous carbon structure at a temperature of at least 3300 °F after said step of partially densifying said porous carbon structure and before said step of subsequently densifying said porous carbon structure.

The process as above wherein said step of heat treating said porous structure follows said pressure gradient CVI/CVD process without removing said porous carbon structure from said CVI/CVD furnace.

A product made by the process as above.

A friction disk, comprising:

a densified annular porous structure having a first carbon matrix deposited within said annular porous structure and a second carbon matrix deposited within said annular porous structure overlying said first carbon matrix, said densified annular porous structure having two generally parallel planar surfaces bounded by an inside circumferential surface and an outside circumferential surface spaced from and encircling said inside circumferential surface, a first circumferential portion adjacent said inside circumferential surface, and a second circumferential portion adjacent said outside circumferential surface, wherein said first and second circumferential portions are bounded by said two generally parallel planar surfaces, said second circumferential portion having at least 10% less of said first carbon matrix per unit volume relative to said first circumferential portion, said first carbon matrix and said second carbon matrix having a substantially rough laminar microstructure, and said first carbon matrix being more graphitized than said second carbon matrix.

The friction disk as above wherein said first carbon matrix and said second carbon matrix have at least 90% rough laminar microstructure.

The friction disk as above wherein said first carbon matrix and said second carbon matrix have at least 95% rough laminar microstructure.

The friction disk as above wherein said first circumferential portion has a greater thermal conductivity normal to said two generally parallel planar surfaces than said second circumferential portion.

The friction disk as above wherein said first circumferential portion has a greater thermal conductivity normal to said first and second circumferential surfaces than said second circumferential portion.

The friction disk as above wherein said first circumferential portion has a greater crushed apparent density than said second circumferential portion.

The friction disk as above wherein said first circumferential portion with has a crushed apparent density at 0.2% greater than said second circumferential portion.

The friction disk as above wherein said first carbon matrix has a greater thermal conductivity than said second carbon matrix.

The friction disk as above wherein said first carbon matrix has a greater density than said second carbon matrix.

The friction disk as above wherein said annular porous structure comprises carbon fibers.

The friction disk as above wherein said densified annular porous structure comprises an annular fibrous structure.

The friction disk as above wherein said densified annular porous structure comprises an annular fibrous structure having carbon fibers.

The friction disk as above wherein said first circumferential portion has a greater thermal conductivity normal to said two generally parallel planar surfaces than said second circumferential portion.

The friction disk as above wherein said first circumferential portion has a greater thermal conductivity normal to said first and second circumferential surfaces than said second circumferential portion.

The friction disk as above wherein said first circumferential portion has a greater crushed apparent density than said second circumferential portion.

The friction disk as above wherein said densified annular porous structure comprises an annular fibrous structure having only carbon fibers.

A friction disk, comprising:

a densified annular fibrous structure having a first carbon matrix deposited within said annular porous structure and a second carbon matrix deposited within said annular porous structure overlying said first carbon matrix, said densified annular porous structure having two generally parallel planar surfaces bounded by an inside circumferential

surface and an outside circumferential surface spaced from and encircling said inside circumferential surface, a first circumferential portion adjacent said inside circumferential surface, and a second circumferential portion adjacent said outside circumferential surface, wherein said first and second circumferential portions are bounded by said two generally parallel planar surfaces, said second circumferential portion having at least 10% less of said first carbon matrix per unit volume relative to said first circumferential portion, said first carbon matrix and said second carbon matrix having a substantially rough laminar microstructure, and said first carbon matrix being more graphitized than said second carbon matrix;

wherein thermal conductivity normal to said two opposing surfaces and crushed apparent density of said densified annular porous structure generally decrease in a radial direction from said inside circumferential surface to said outside circumferential surface.

The friction disk as above wherein said densified annular fibrous structure comprises carbon fibers.
A CVI/CVD process in a CVI/CVD furnace, comprising the steps of:

introducing a reactant gas into a sealed preheater disposed within said CVI/CVD furnace, said sealed preheater having a preheater inlet and a preheater outlet, said reactant gas being introduced into said preheater inlet and exiting said sealed preheater through said preheater outlet and infiltrating at least one porous structure disposed within said CVI/CVD furnace;

heating said at least one porous structure;

heating said sealed preheater to a preheater temperature greater than said reactant gas temperature;

sensing a gas temperature of said reactant gas proximate said outlet;

adjusting said preheater temperature to achieve a desired gas temperature; and,

exhausting said reactant gas from said CVI/CVD furnace.

The process as above wherein said CVI/CVD furnace comprises a susceptor wall, and further comprising the step of heating said susceptor wall, and said step of heating said sealed preheater comprises the step of radiating heat energy from said susceptor wall to said sealed preheater.

The process as above wherein said sealed preheater is disposed in close proximity to said susceptor wall.

The process as above wherein said CVI/CVD furnace comprises a susceptor wall having at least first and second susceptor wall portions and at least first and second induction coils, said first induction coil being inductively coupled to said first susceptor wall in a manner that transforms electrical energy from said first induction coil to heat energy in said first susceptor wall, and said second induction coil being inductively coupled to said second susceptor wall portion in a manner that transforms electrical energy from said second induction coil to heat energy in said second susceptor wall portion, said sealed preheater being disposed proximate said first susceptor wall portion and being heated to said preheater temperature at least in part by radiant heat energy from said first susceptor wall portion; and

wherein said step of adjusting said heat exchanger temperature comprises the step of adjusting electrical power to said first induction coil.

The process as above wherein said CVI/CVD furnace comprises a cylindrical susceptor wall having at least first and second cylindrical susceptor wall portions and at least first and second cylindrical induction coils, said first cylindrical induction coil being concentrically disposed around and inductively coupled to said first cylindrical susceptor wall in a manner that transforms electrical energy from said first cylindrical induction coil to heat energy in said first cylindrical susceptor wall, and said second cylindrical induction coil being concentrically disposed around and inductively coupled to said second cylindrical susceptor wall portion in a manner that transforms electrical energy from said second cylindrical induction coil to heat energy in said second cylindrical susceptor wall portion, said sealed preheater defines a generally cylindrical preheater perimeter concentrically disposed within and in close proximity to said first cylindrical susceptor wall portion and being heated to said preheater temperature at least in part by radiant heat energy from said first cylindrical susceptor wall portion; and

wherein said step of adjusting said preheater temperature comprises the step of adjusting electrical power to said first induction coil.

The process as above wherein said CVI/CVD furnace comprises a generally cylindrical susceptor wall, and said sealed preheater comprises a generally arcuate preheater perimeter in close proximity to said cylindrical susceptor wall.

The process as above wherein said sealed preheater is resistance heated by electrical energy.

The process as above wherein said preheater outlet comprises an array of perforations.

The process as above wherein said at least one porous structure comprises a first portion and a second portion; and,

further comprising the step of forcing said reactant gas to pass through said at least one porous structure from said first portion to said second portion.

The process as above wherein said reactant gas deposits a carbon matrix having a substantially rough laminar microstructure within said at least one porous structure.

The process as above wherein said at least one porous structure is a carbon porous structure, and said reactant gas deposits a carbon matrix within said at least one porous structure.

5 The process as above wherein said at least one porous structure comprises a plurality of annular porous structures disposed in a stack that defines an annular porous wall; and,

further comprising the step of forcing dispersion of said reactant gas through said annular porous wall by introducing said reactant gas to said CVI/CVD furnace and exhausting said reactant gas from said CVI/CVD furnace on opposite sides of said annular porous wall.

10 The process as above wherein each annular porous structure has a surface area, said stack of annular porous structures having at least one ring concentrically disposed between each pair of adjacent porous structures with a majority of said surface area of each annular porous structure being exposed to said reactant gas.

The process as above wherein said stack defines an enclosed cavity bounded by said annular porous wall; and,

15 further comprising the step of introducing said reactant gas from said preheater outlet into said enclosed cavity, said enclosed cavity being sealed to said preheater outlet.

A CVI/CVD process in a CVI/CVD furnace, comprising the steps of:

forming an annular porous wall that defines an enclosed cavity, said porous annular wall including a stack of annular fibrous carbon structures;

20 sealing said annular porous wall to a sealed preheater, said sealed preheater having a preheater inlet and a preheater outlet, said enclosed cavity being in fluid communication with said gas outlet;

introducing a carbon bearing reactant gas into said preheater inlet, directing said gas through said sealed preheater, to said preheater outlet, and into said enclosed cavity;

heating said annular porous wall;

25 heating said preheater to a preheater temperature greater than a gas temperature of said reactant gas proximate said preheater inlet;

sensing a gas temperature of said reactant gas proximate said preheater outlet;

adjusting said preheater temperature to achieve a desired gas temperature; and,

30 withdrawing said reactant gas from said CVI/CVD furnace on a side of said annular porous wall opposite said enclosed cavity thereby forcing dispersion of said reactant gas introduced into said enclosed cavity through said annular porous wall.

The process as above wherein said CVI/CVD furnace comprises a susceptor wall having at least first and second susceptor wall portions and at least first and second induction coils, said first induction coil being inductively coupled to said first susceptor wall in a manner that transforms electrical energy from said first induction coil to heat energy in said first susceptor wall, and said second induction coil being inductively coupled to said second susceptor wall portion in a manner that transforms electrical energy from said second induction coil to heat energy in said second susceptor wall portion, said preheater being disposed proximate said first susceptor wall portion and being heated to said preheater temperature at least in part by radiant heat energy from said first susceptor wall portion; and

40 wherein said step of adjusting said preheater temperature comprises the step of adjusting electrical power to said first induction coil.

The process as above wherein said reactant gas deposits a carbon matrix having a substantially rough laminar microstructure within said annular porous wall.

45 The process as above wherein each annular fibrous carbon structure has a surface area, said stack having at least one ring concentrically disposed between each pair of adjacent annular fibrous carbon structures with a majority of said surface area of each annular fibrous carbon structure being exposed to said reactant gas.

An apparatus for introducing a first reactant gas into a CVI/CVD furnace, comprising:

50 a first main gas line for supplying the first reactant gas;

a plurality of furnace supply lines in fluid communication with said first main gas line and the CVI/CVD furnace;

a plurality of first flow meters that measure a quantity of first reactant gas flow through each furnace supply line; and,

55 a plurality of first control valves configured to control said quantity of flow of the first reactant gas through each furnace supply line.

The apparatus as above wherein said quantity of flow is different for each furnace supply line.

The apparatus as above wherein said plurality of first flow meters communicate with a controller, said controller

controlling said plurality of first control valves.

The apparatus as above wherein each furnace supply line comprises one first flow meter and one first control valve, said one first flow meter communicating with a controller, said controller controlling said one first control valve.

The apparatus as above further comprising a first main control valve disposed within said first main gas line.

5 The apparatus as above wherein a second reactant gas is supplied to the CVI/CVD furnace, further comprising:

a second main gas line for supplying the second reactant gas;

a plurality of second flow meters that measure a quantity of second reactant gas flow through each furnace supply line; and,

10 a plurality of second control valves configured to control said quantity of flow of the second reactant gas through each furnace supply line.

An apparatus for CVI/CVD densifying a plurality of porous structures, comprising:

15 a CVI/CVD furnace that defines a furnace volume;

a vacuum apparatus in fluid communication with said furnace volume;

a first main gas line for supplying a first reactant gas;

a plurality of furnace supply lines in fluid communication with said first main gas line; and,

20 a plurality of stacks of the porous structures disposed within said furnace volume, each stack defining an enclosed cavity in fluid communication with a different furnace supply line and sealed within said furnace volume such that a reactant gas flow introduced into each enclosed cavity through said one furnace supply line is forced to disperse through said porous structures before being withdrawn from said furnace volume by said vacuum apparatus.

The apparatus as above further comprising a first main control valve disposed within said first main supply line.

25 The apparatus as above further comprising:

a plurality of first flow meters that measure a quantity of first reactant gas flow through each furnace supply line; and,

30 a plurality of first control valves configured to control said quantity of flow of the first reactant gas through each furnace supply line.

The apparatus as above wherein said quantity of first reactant gas, flow is different for each furnace supply line.

The apparatus as above wherein each furnace supply line comprises one first flow meter and one first control valve, said one first flow meter communicating with a controller, said controller controlling said one first control valve.

35 The apparatus as above further comprising:

a second main gas line for supplying a second reactant gas, said furnace supply lines being in fluid communication with said second main gas line.

40 The apparatus as above further comprising:

a plurality of second flow meters that measure a quantity of second reactant gas flow through each furnace supply line; and,

45 a plurality of second control valves configured to control said quantity of flow of said second reactant gas through each furnace supply line.

A CVI/CVD densification process, comprising the steps of:

50 densifying a first porous wall within a CVI/CVD furnace by a pressure gradient CVI/CVD process wherein a first flow of reactant gas is forced to disperse through said first porous wall;

densifying a second porous wall by a pressure gradient CVI/CVD process wherein a second flow of reactant gas is forced to disperse through said second porous wall; and,

independently controlling said first flow of said reactant gas and said second flow of said reactant gas.

55 The process as above further comprising the steps of:

densifying at least a third porous wall by a pressure gradient CVI/CVD process wherein at least a third flow of reactant gas is forced to disperse through at least said third porous wall; and

Independently controlling at least said third flow of reactant gas.

The process as above further comprising the steps of:

- 5 sensing a first porous wall temperature; and,
controlling said first porous wall temperature by increasing or decreasing said first flow of reactant gas.

The process as above further comprising the steps of:

- 10 sensing a second porous wall temperature; and,
controlling said second porous wall temperature by increasing or decreasing said second flow of reactant gas.

The process as above wherein:

- 15 said step of densifying said first porous wall includes the step of subjecting one side of said first porous wall to said first flow of reactant gas at a first pressure and an opposing side of said first porous wall to a vacuum pressure, said first pressure being greater than said vacuum pressure; and,
said step of densifying said second porous wall includes the step of subjecting one side of said second porous wall to said second flow of reactant gas at a second pressure and an opposing side of said second porous wall to a vacuum pressure, said second pressure being greater than said vacuum pressure
- 20

The process as above further comprising the steps of:

- 25 sensing said first pressure; and,
controlling said first pressure by increasing or decreasing said first flow of reactant gas.

The process as above further comprising the steps of:

- 30 sensing said second pressure; and,
controlling said second pressure by increasing or decreasing said second flow of reactant gas.

Claims

1. A CVI/CVD process in a CVI/CVD furnace, comprising the steps of:

- 35 Introducing a reactant gas into a sealed preheater disposed within said CVI/CVD furnace, said sealed preheater having a preheater inlet and a preheater outlet, said reactant gas being introduced into said preheater inlet and exiting said sealed preheater through said preheater outlet and infiltrating at least one porous structure disposed within said CVI/CVD furnace;
40 heating said at least one porous structure;
heating said sealed preheater to a preheater temperature greater than said reactant gas temperature;
sensing a gas temperature of said reactant gas proximate said outlet;
adjusting said preheater temperature to achieve a desired gas temperature; and,
45 exhausting said reactant gas from said CVI/CVD furnace.

2. The process of claim 1, wherein said CVI/CVD furnace comprises a susceptor wall, and further comprising the step of heating said susceptor wall, and said step of heating said sealed preheater comprises the step of radiating heat energy from said susceptor wall to said sealed preheater.

3. The process of claim 1, wherein said sealed preheater is disposed in close proximity to said susceptor wall.

4. The process of claim 1, wherein said CVI/CVD furnace comprises a susceptor wall having at least first and second susceptor wall portions and at least first and second induction coils, said first induction coil being inductively coupled to said first susceptor wall in a manner that transforms electrical energy from said first induction coil to heat energy in said first susceptor wall, and said second induction coil being inductively coupled to said second susceptor wall portion in a manner that transforms electrical energy from said second induction coil to heat energy in said second susceptor wall portion, said sealed preheater being disposed proximate said first susceptor wall portion and being heated to said preheater temperature at least in part by radiant heat energy from said first susceptor wall
- 55

portion; and

wherein said step of adjusting said heat exchanger temperature comprises the step of adjusting electrical power to said first induction coil.

- 5 5. The process of claim 1, wherein said CVI/CVD furnace comprises a cylindrical susceptor wall having at least first and second cylindrical susceptor wall portions and at least first and second cylindrical induction coils, said first cylindrical induction coil being concentrically disposed around and inductively coupled to said first cylindrical susceptor wall in a manner that transforms electrical energy from said first cylindrical induction coil to heat energy in said first cylindrical susceptor wall, and said second cylindrical induction coil being concentrically disposed around
10 and inductively coupled to said second cylindrical susceptor wall portion in a manner that transforms electrical energy from said second cylindrical induction coil to heat energy in said second cylindrical susceptor wall portion, said sealed preheater defines a generally cylindrical preheater perimeter concentrically disposed within and in close proximity to said first cylindrical susceptor wall portion and being heated to said preheater temperature at least in part by radiant heat energy from said first cylindrical susceptor wall portion; and
15 wherein said step of adjusting said preheater temperature comprises the step of adjusting electrical power to said first induction coil.
6. The process of claim 1, wherein said CVI/CVD furnace comprises a generally cylindrical susceptor wall, and said sealed preheater comprises a generally arcuate preheater perimeter in close proximity to said cylindrical susceptor wall.
20
7. The process of claim 1, wherein said sealed preheater is resistance heated by electrical energy.
8. The process of claim 1, wherein said preheater outlet comprises an array of perforations.
25
9. The process of claim 1, wherein said reactant gas deposits a carbon matrix having a substantially rough laminar microstructure within said at least one porous structure.
10. The process of claim 1, wherein said at least one porous structure is a carbon porous structure, and said reactant gas deposits a carbon matrix within said at least one porous structure.

㉙ Treatment of a surface by laser energy.

㉙ In treating the surface of a material (22) with laser energy by sweeping a laser beam (12) over the surface, a substantial uniformity (30) of energy delivery is achieved across a major portion of the transverse (x) width of the beam (12) by using an unfocussed beam of a ring mode configuration and preferably one having an outer ring (14) with at least some degree of interior fill (16) as is achieved by a laser beam continuing TEM₀₀ and TEM₀₁ modes. The specification discusses various beam configurations. The specification introduces the concept of "exposure integration" which is a function not only of the beam profile in the sweep direction (z) but of the rate of sweep. An exposure duration for any scanned point (P) of not more than 10 milliseconds is suggested. The application of the invention is particularly described with reference to marking the surface of paper.

Treatment of a surface by laser energy

This invention relates to the treatment of the surface of a material by laser energy and is concerned with a method and apparatus for such treatment. One particular application of the invention is to the marking of the surface of a web of paper by application thereto of laser energy. Such marking may be the application to the web of a repeated logo or other visual mark short of perforating the web or producing an undue charring of the paper that would be aesthetically unacceptable. However, the principles of the invention are considered to be of more general utility in cases where a surface of a material is treated by scanning a laser beam thereover to effect a change at the surface. Such change may or may not be visible.

One such use of laser energy involves the scanning of a beam relative to the web surface to produce a "mark" having both length in the scanning direction and a significant width transverse to this direction. The width may be several millimeters. The mark, logo or whatever applied to the material surface may be made with the aid of a mask or stencil and should present a uniform appearance. This requires seeking a uniformity of effect from the delivery of the scanning laser energy.

An example of marking a paper web by a laser beam with the aid of an image-bearing mask is disclosed in European patent specification EP-A 0278505. In this specification, it is shown how a laser beam may be brought to a line focus, the line extending the required width in the direction transverse to the scan direction. In the embodiments disclosed in that specification the mask is scanned past the fixed line provided by the beam.

Copending European patent application 89301486.0 filed 16th February, 1989 and published under the number EP-A 0329438 on 23rd August, 1989 discloses another arrangement using a laser beam for marking a web with the aid of a mask or stencil. In this case an unfocussed, but collimated, laser beam is employed. The beam has a cross-section whose diameter satisfies the width requirement of the image transverse to the direction of scan.

The present invention has arisen out of work done in investigating the uniformity of marking obtained when a laser beam is scanned relative to the surface of a material, and more particularly the uniformity in the direction normal to the scan direction. More generally this has led to the consideration of obtaining a uniform treatment of the surface or surface zone of a material by scanning a laser beam thereover in which energy is applied over a significant width transverse to the scan

direction.

At the same time as seeking to achieve this uniformity, it is desirable to achieve an efficient utilisation of the beam and to avoid having to use a laser of unduly excessive power. Take for example, a beam having a simple circularly symmetrical, Gaussian distribution, i.e. a TEM₀₀ mode beam. It has a high central peak of irradiance rapidly dropping to low irradiance levels away from the centre. It will be readily appreciated that the strip irradiated by such a beam on sweeping a surface will receive a far greater total exposure where the peak sweeps than at the lateral margins. More uniform exposure can be achieved by truncating the beam - that is masking off the lateral portions - to concentrate on the central area. This reduces the width of strip treated as well as wasting a substantial portion of the beam power. If the beam diameter is increased to make up for the lost width, then a higher power laser is required to achieve the same irradiance in the active portion of the beam.

We shall describe hereinafter how by proper selection of the operating mode of the laser, and specifically by use of a ring mode laser, it is possible to achieve a substantially uniform delivery of energy across a major proportion of the scanned width of an untruncated beam. That is to say that the efficiency of utilisation of the beam is good if the beam is truncated to the appropriate proportion; or put another way for a given width scanned, the required power of the laser may be kept to a minimum for the surface treatment required. More particularly, it has now been discovered that to achieve these desirable results the rate of scan of the beam should be such as to result in an integrated effect on the material treated to which the name "exposure integration" is given.

According to one aspect of the present invention there is provided a method of treating the surface of material with laser energy in which a laser beam is scanned relative to the surface, characterised in that:

the laser beam is unfocussed at the surface, the cross-section of the beam at the surface has a significant width transverse to the direction of scan, the cross-section of the beam at the surface exhibits an intensity distribution distinctive of the propagation mode structure of the beam, the mode structure comprises a ring mode, and the scanning velocity of the beam relative to the material is such that at any scanned point on the surface, the thermal energy generated is a function of the integral of the beam irradiance profile acting at that point as the beam traverses the point.

In another aspect of the invention, there is

provided a method of treating the surface of material with laser energy in which a laser beam is scanned relative to the surface, characterised in that:

the laser beam is unfocussed at the surface,
the cross-section of the beam at the surface has a significant width transverse to the direction of scan,
the cross-section of the beam at the surface exhibits an intensity distribution distinctive of the propagation mode structure of the beam,
the mode structure comprises a ring mode, and
the scanning velocity of the beam relative to the material is such that at any scanned point on the surface, the exposure duration is sufficiently short to ensure that the point responds to the integrated energy derived from the beam irradiance profile acting at that point as the beam traverses the point.

The ring mode structure referred to in the above defined methods may be circularly symmetrical. Preferably the intensity distribution of the mode structure comprises an outer ring and a central peak. This mode structure may be achieved by the combination of TEM_{00} and TEM_{01} modes.

A specific application of the invention to the treatment or imaging of paper and the laser power used is below a level at which significant charring occurs. Present experience indicates that were the material is paper, the exposure duration should be not more than 10 milliseconds.

In yet another aspect of the invention, there is provided apparatus for treating the surface of a material with laser energy comprising:

a laser providing a beam with a ring mode structure,

a material surface receiving location,

means for directing the laser beam to said location as a non-focussed beam having a significant dimension in a predetermined direction,

means for effecting a relative scanning motion between the beam and a material surface received at said location in a direction substantially normal to said predetermined direction, said scanning-effecting means providing a scanning velocity such that at any scanned point on the material surface, the thermal energy generated is a function of the integral of the beam irradiance profile acting at that point.

In the above apparatus the laser beam may be circularly symmetrical. A preferred ring mode structure has an outer ring encircling a central peak. This structure may be achieved by the combination of TEM_{00} and TEM_{01} modes.

Preferably for paper at least, the scanning-effecting means provides an exposure duration for any scanned point that is not more than 10 milliseconds.

This invention and its practice will be further described with reference to the accompanying

drawings in which;

Fig. 1 shows a laser beam scanning the surface of a material to be treated, and the profile of a diametric intensity distribution for the beam;

Fig. 2A shows a representation of the beam intensity as a three-dimensional figure;

Fig. 2B shows an energy distribution curve across the width of the strip on the surface scanned by the beam;

Fig. 3A shows a preferred irradiance profile for the laser beam;

Fig. 3B illustrates the positions of the profiles illustrated in Fig. 4;

Figs. 4A to 4D shows irradiance profiles for four different "slices" through the beam;

Fig. 5 is a graph showing the power distribution profile for the z-direction slices through a beam having the diametric irradiance profile of Fig. 3A;

Fig. 6 is a graph showing the accumulation of radiant exposure as points on the surface are scanned with the slice irradiance profiles of Fig. 4A to 4D;

Fig. 7 shows slice profiles through a ring-mode beam having a central zero irradiance;

Fig. 8 is a graph similar to that of Fig. 5 for the beam of Fig. 7;

Fig. 9 shows a graph similar to that of Figs. 5 and 8 for a beam having a theoretical "top-hat" profile; and

Fig. 10 shows one diagrammatic example of apparatus embodying this invention.

Fig. 1 shows a laser beam 10 sweeping across the surface 20 of a material to sweep a path 22 of width L_x , which in this example is equal to the diameter d of the beam. The beam is swept in the direction of arrows Z . The manner in which the relative movement between beam and the material surface is achieved is not relevant to this discussion. It is assumed the beam impinges substantially normally to the material surface. The beam may be utilized to apply a logo to the surface 20 by sweeping it across a mask or stencil such as that seen in Fig. 10 of EP-A 0279505. However, the following discussion is concerned generally with the energy delivered to points across the width of path 22.

The beam 10 illustrated is an example of a ring mode of operation of the laser source. The cross-section 12 of the beam is shown in a simplified form as having an outer peripheral ring 14 and an inner central peak 16. The irradiance distribution of the beam is circularly symmetrical in a cross-section through the beam and this form of beam can be realised by a laser operating in a $TEM_{00} + TEM_{01}$ mode. The TEM_{00} mode produces the central peak, the TEM_{01} mode produces the outer ring. A diametric beam integrated energy profile

is shown upstanding from path 22. The integrated energy distribution is illustrated and discussed more fully below. In this description the irradiance (power density) of the beam will be denoted by E (in W/m^2). The direction of beam sweep will be denoted by z and the transverse direction by x .

Fig. 2A illustrates one half of a typical irradiance distribution as a three-dimensional profile. The diametric slice taken across the profile is plotted in Fig. 3A. Fig. 2B shows the simplified beam cross-section 12 sweeping along path 22. To the right of the figure a curve is plotted in stepwise increments for the total energy density or radiant exposure H (in $Joules/m^2$) delivered to any point such as P_x in the path of the beam lying at a distance x from the central longitudinal axis z_0 . Because the beam is symmetrical, $x = 0$ will be taken to lie on axis z_0 and distances x measured as offset distances from this axis: in some of the later description x is expressed as a fraction of beam radius. The energy delivered to any point P_x - represented as a small area of finite width in the x direction - is proportional to the integral of the slice 18 in the z -axis direction through the beam irradiance distribution of Fig. 2A that traverses P_x during the sweep. What curve 30 shows is that the energy delivered is remarkably uniform over a substantial proportion of the width L_x , i.e. the beam diameter d . The energy delivered only drops at the extremities where the profile slice acting on a point such as P_x becomes almost tangential to the beam. It will be appreciated that the margins of the beam where the total energy delivered drops can be masked off to truncate the beam cross-section in the x direction to that portion at which the near uniform energy delivery is obtained.

Turning now to a more specific example, Fig. 3A shows a diametric slice through the beam irradiance (E) distribution for a combined TEM_{00} and TEM_{01} modes such as illustrated in Fig. 2A. The central peak 16 has an amplitude approximating the peak amplitude of the ring 14. The diameter of the peak of the outer ring is denoted ϕ . In contrast to the simplified diagrams, it will be seen that the fall away of the central peak and of the outer ring from the peak values is such that between the two is a valley 18 whose minimum amplitude is still substantial. In the case illustrated it is somewhat in excess of half the peak value. The profile in Fig. 3A is for the irradiance of the beam along the diametric axis x in Fig. 3B.

Figs. 4A to 4D show irradiance profiles taken along z -axis directed slices at distances x_1 , x_2 , x_3 and x_4 respectively from the central axis z_0 ($x = 0$). These slices are shown in Fig. 3B. In fact what is shown in each case is a half-profile: the complete profile is symmetric about the diametric x -axis of Fig. 3B which lies at $Z = 0$ in Figs. 4A-D.

As will be apparent from Figs. 4A-D, the irradiance profile increasingly departs from that of Fig. 3A as x increases. It will also be noted that the extent of the profile in the z direction decreases with increasing x to become vanishingly small as x approaches the beam radius - the tangential condition. Thus any point P_x at distances x_1 , x_2 , x_3 and x_4 will be scanned by the irradiance profile of Fig. 4A, 4B, 4C or 4D respectively, a central axis point being scanned by the profile of Fig. 3A.

The power available to act on a single point in the path of a profile slice at the distances x_1 , x_2 , x_3 , x_4 etc. is illustrated in Fig. 5 in which the abscissa again represents x . The ordinate H is the integral of the slice profile in the z direction for each value of x and represents the power in the slice for an arbitrarily small slice width δx . (dP/dx) or alternatively can be expressed in terms of the radiant exposure (energy per unit area deliverable) in J/m^2 for a point at a distance x from the central axis and scanned by the pertinent slice profile as the beam moves across the material surface at constant velocity. The total energy delivered will of course depend on the beam velocity, a factor to be discussed later.

The delivery of energy to points lying at the distances x_1 , x_2 , x_3 and x_4 is further illustrated in Fig. 6 which shows how the total energy, ΣH , accumulates with time as the beam is scanned. From Figs. 5 and 6 it is seen that at distances x_1 , x_2 , x_3 all within the radius ϕ , the energies delivered and the rate at which energy is delivered are closely comparable. At x_4 beyond the peak of the outer ring, the energy is beginning to fall significantly.

What the foregoing shows is that the ring mode laser beam illustrated is capable of delivering a substantially uniform amount of energy to a strip of material scanned by the beam, notwithstanding the apparently widely different irradiance values available in the beam cross-section. If a strip of material surface is to receive substantially the same energy, the beam can be truncated or masked in the x direction to remove the lateral margins. It is desirable that if this is done, the amount of beam power lost should not be too great. This can be expressed as truncation efficiency, that is the proportion of total beam power available when the lateral extent of the active beam is restricted to a given fraction of the diameter. The combined $TEM_{00} + TEM_{01}$ is considered favourable in this respect.

The analysis so far has considered the case where the central peak 16 does not exceed the peak of the outer ring 14 by any great amount. On one extreme is the case where the central peak entirely predominates, i.e. virtually a TEM_{00} beam having a Gaussian distribution about its centre. This is no longer a ring mode. As has already been

pointed out in the introductory portion of this specification, such a beam cannot combine efficient beam utilisation with uniform energy delivery to a strip of material. At the other extreme, the beam can virtually lose the central peak to just leave the outer ring. Fig. 7 shows a set of profiles in the z-axis direction for a TEM_{01} mode beam with a centre or on-axis zero. Profiles are taken for x values of 0, 0.2, 0.4 and 0.6 expressed as a fraction of beam radius, the irradiance value on the y-axis being normalized to unity for the peak value. The energy deliverable along profile slices in the z-direction (also expressed as a fraction of beam radius) or to put it in other words, the power contained in slices of a width δx , is illustrated as curve 40 in Fig. 8 which is plotted in the same terms as, and should be compared with, Fig. 5. The y-axis scale in Fig. 8 is normalised to unity at the peak value. Instead of the slight peak on the axis z_0 in Fig. 5, Fig. 8 shows a dip on the zero axis, though for values of x to about 0.55 the uniformity of radiant exposure is about $\pm 10\%$ taking the 0.9 ordinate value as the datum. The variation in exposure acceptable will depend on the particular application but the figure quoted is one presently considered reasonable, particularly in the light of experience in marking paper. It is clear, however, that a TEM_{00} mode component is of benefit in obtaining a more uniform energy distribution.

Fig. 8 also shows a curve 50 which represents the truncation efficiency expressed as a fraction on the y-axis. In accord with the definition given above this is the fraction of beam power allowed through a slit of width $2x$ (beam diameter is 2) whose longitudinal axis lies on the z_0 axis: that is the curve 50 as plotted shows the fractional truncational efficiency for a slit of half-width x . The truncation efficiency at the $x = 0.55$ value just discussed is 0.8.

To further explore the limits of usable beam profiles, consider a theoretical profile which can be termed a "top-hat" profile. In a representation of the kind seen in Fig. 2A this profile would be a right cylinder of radius d and in a diametric profile of the kind shown in Fig. 3A would have a rectangular (flat top) profile across the full-beam diameter. Fig. 9 shows in curve 42 the power contained in slice profiles as is done in Fig. 8, and in curve 52 the truncation efficiency. For a truncated beam having the same $\pm 10\%$ radiant exposure about the same 0.9 datum as in Fig. 8, the slit half-width is slightly greater at 0.6, so it is a little more efficient in beam utilisation. For comparison, the embodiment of Figs. 2 and 3 provides a truncation efficiency of about 85% for a slit half-width slightly greater than 0.6.

All the examples illustrated are ring modes.

The single outer ring with centre zero is the simplest case. The top-hat profile is more akin to the combined $TEM_{00} + TEM_{01}$ analysed earlier but with a uniform fill across the whole beam. It is possible to generate multi-mode beams comprising large numbers of higher-order modes which have a central circular plateau, albeit with secondary peaks imposed on this and without of course, having exactly vertical edges. What has emerged from the investigation made so far is that in addition to the ring mode itself, a central peak is beneficial: where there is a central intensity peak, the value of it should preferably be about that of the outer ring or not much in excess of it to obtain a reasonably uniform energy delivery across a major proportion of the beam width transverse to the scan direction.

The foregoing analysis of various beam profiles has demonstrated the capability of ring modes to deliver a substantially uniform amount of energy to points along the strip of material traversed by the beam over a major proportion of the beam diameter. However, it is necessary for the scanning velocity of the beam to be sufficient to achieve exposure integration. This will now be further explained.

If we take the presently preferred kind of profile such as shown in Fig. 2A ($TEM_{00} + TEM_{01}$), it is necessary that the beam sweep at a velocity such that the material surface does not respond to the fine structure of the beam profile. Investigation has shown that at low speeds paper responds to the rate of energy delivery, and for example along the z_0 axis would respond to the three peaks of the profile of Fig. 3A. In order to have the paper respond to the integrated energy, such as shown at 30 in Fig. 2B and in greater detail in Figs. 5 and 6, it is considered necessary to have an exposure duration less than about 10 milliseconds. This has been specifically investigated on a paper having a weight of about 50 g/m². The exposure duration is the time for which a point swept by the beam is exposed to the pertinent slice profile. The maximum exposure duration is thus along the z_0 axis where the profile is the full beam diameter d . The scanning velocity must therefore be in excess of $d/10$ m/s, where d is in mm., which is about 80 m/s in the present case.

In general in considering the exposure duration, it is required that, in the time taken for the beam to sweep across any given point on the surface of the material being treated, significant thermal relaxation effects should not have occurred, and that therefore the material responds to the total energy delivery rather than to the rate of delivery (power) during the exposure period.

In the case of marking paper which has been particularly discussed, we are concerned with the conversion of the impinging radiant energy to ther-

mal energy which then produces an effect in a surface-adjacent zone of the material. Paper is fibrous and has a highly open structure as seen at the laser wavelength. Light will be multiply scattered by the fibres near the surface as it penetrates into the open structure and is relatively gradually absorbed and converted to heat. In addition paper is a complex material. In particular its fibrous structure can be expected to include a few percent by weight of moisture even if the paper is notionally dry. Thus any heat generated will in part at least act to drive off this water before the heat will much affect the cellulose.

In the sort of marking application mentioned earlier, the heat generated by the impinging laser beam is believed to alter the fibrous structure in some way, perhaps as a result of first evaporating moisture, before any charring of the fibres begins. This alteration of the fibrous structure may itself produce a visible mark. There may then follow a charring of the fibres but without burning them away. It has been found that by the application of exposure integration as described in this specification it has proved possible to provide a logo or similar mark on a paper web which has a good uniform, visual appearance without being unduly pronounced.

Fig. 10 diagrammatically illustrates one apparatus for generating a laser beam to sweep a material surface such as shown in Figs. 1, 2 and 2A. In Fig. 10 a laser 100 is used to generate a beam 110 that is directed along a beam path 112 to a web path 114. A material such as a paper web is transported along this path from say one reel 116 to another 117 with appropriate rollers 118 as will be understood in the art. The path could be within a paper-making machine. The beam 110 impinges on the web path 114 and longitudinally scans the path by virtue of the web transport. The beam impinging on the web at location 120 is the unfocussed, collimated beam of ring mode structure discussed above.

The beam may be used with an imaging mask, which may involve applying an optical scanning motion to the beam itself. The use of such image scanning for marking a moving web with an unfocussed, collimated, laser beam is described in EP-A 0329438 mentioned above.

Claims

1. A method of treating the surface of material with laser energy in which a laser beam is scanned relative to the surface, characterised in that: the laser beam is unfocussed at the surface, the cross-section of the beam at the surface has a significant width transverse to the direction of scan,

the cross-section of the beam at the surface exhibits an intensity distribution distinctive of the propagation mode structure of the beam,

the mode structure comprises a ring mode, and

the scanning velocity of the beam relative to the material is such that at any scanned point on the surface, the thermal energy generated is a function of the integral of the beam irradiance profile acting at that point as the beam traverses the point.

2. A method as claimed in Claim 1 in which said ring mode structure is circularly symmetrical.

3. A method as claimed in Claim 1 or 2 in which the intensity distribution of said mode structure comprises an outer ring and a central peak.

4. A method as claimed in Claim 3 in which the mode structure comprises the combination of TEM_{00} and TEM_{01} modes.

5. A method as claimed in any preceding claim in which the material is paper and the laser power is below a level at which significant charring occurs.

6. A method as claimed in any one of Claims 1 to 4 in which the material is paper and the exposure duration is not more than 10 milliseconds.

7. Apparatus for treating the surface of a material with laser energy comprising:

a laser providing a beam with a ring mode structure,

a material surface receiving location,

means for directing the laser beam to said location as a non-focussed beam having a significant dimension in a predetermined direction,

means for effecting a relative scanning motion between the beam and a material surface received at said location in a direction substantially normal to said predetermined direction, said scanning-effecting means providing a scanning velocity such that at any scanned point on the material surface, the thermal energy generated is a function of the integral of the beam irradiance profile acting at that point.

8. Apparatus as claimed in Claim 7 in which said laser beam is circularly symmetrical.

9. Apparatus as claimed in Claim 7 or 8 in which said ring mode structure has an outer ring encircling a central peak.

10. Apparatus as claimed in Claim 9 in which the mode structure comprises the combination of TEM_{00} and TEM_{01} modes.

11. Apparatus as claimed in any one of Claims 7 to 10 wherein said scanning-effecting means provides an exposure duration for any scanned point that is not more than 10 milliseconds.

12. A method of treating the surface of material with laser energy in which a laser beam is scanned relative to the surface, characterised in that: the laser beam is unfocussed at the surface, the cross-section of the beam at the surface has a

significant width transverse to the direction of scan, the cross-section of the beam at the surface exhibits an intensity distribution distinctive of the propagation mode structure of the beam,

the mode structure comprises a ring mode, and the scanning velocity of the beam relative to the material is such that at any scanned point on the surface, the exposure duration is sufficiently short to ensure that the point responds to the integrated energy derived from the beam irradiance profile acting at that point as the beam traverses the point.

13. A method as claimed in Claim 12 in which said ring mode structure is circularly symmetrical.

14. A method as claimed in Claim 12 or 13 in which the intensity distribution of said mode structure comprises an outer ring and a central peak.

15. A method as claimed in Claim 14 in which the mode structure comprises the combination of TEM_{00} and TEM_{01} modes.

16. A method as claimed in any one of Claims 12 to 15 in which the material is paper and the laser power is below a level at which significant charring occurs.

17. A method as claimed in any one of Claims 12 to 15 in which the material is paper and the exposure duration for any scanned point is not more than 10 milliseconds.
